6.1 General Topics

6.1.1 CodeIgniter URLs

By default, URLs in CodeIgniter are designed to be search-engine and human friendly. Rather than using the standard “query string” approach to URLs that is synonymous with dynamic systems, CodeIgniter uses a **segment-based** approach:

```
example.com/news/article/my_article
```

: Query string URLs can be optionally enabled, as described below.

URI Segments

The segments in the URL, in following with the Model-View-Controller approach, usually represent:

```
example.com/class/function/ID
```

1. The first segment represents the controller **class** that should be invoked.
2. The second segment represents the class **function**, or method, that should be called.
3. The third, and any additional segments, represent the ID and any variables that will be passed to the controller.

The *URI Library* and the *URL Helper* contain functions that make it easy to work with your URI data. In addition, your URLs can be remapped using the *URI Routing* feature for more flexibility.

Removing the index.php file

By default, the **index.php** file will be included in your URLs:

```
example.com/index.php/news/article/my_article
```

If your Apache server has *mod_rewrite* enabled, you can easily remove this file by using a *.htaccess* file with some simple rules. Here is an example of such a file, using the “negative” method in which everything is redirected except the specified items:

```
RewriteEngine On
RewriteCond %{REQUEST_FILENAME} !-f
RewriteCond %{REQUEST_FILENAME} !-d
RewriteRule ^(.*)$ index.php/$1 [L]
```

In the above example, any HTTP request other than those for existing directories and existing files is treated as a request for your `index.php` file.

: These specific rules might not work for all server configurations.

: Make sure to also exclude from the above rule any assets that you might need to be accessible from the outside world.

Adding a URL Suffix

In your **config/config.php** file you can specify a suffix that will be added to all URLs generated by CodeIgniter. For example, if a URL is this:

```
example.com/index.php/products/view/shoes
```

You can optionally add a suffix, like **.html**, making the page appear to be of a certain type:

```
example.com/index.php/products/view/shoes.html
```

Enabling Query Strings

In some cases you might prefer to use query strings URLs:

```
index.php?c=products&m=view&id=345
```

CodeIgniter optionally supports this capability, which can be enabled in your **application/config.php** file. If you open your config file you'll see these items:

```
$config['enable_query_strings'] = FALSE;
$config['controller_trigger'] = 'c';
$config['function_trigger'] = 'm';
```

If you change “enable_query_strings” to TRUE this feature will become active. Your controllers and functions will then be accessible using the “trigger” words you’ve set to invoke your controllers and methods:

```
index.php?c=controller&m=method
```

: If you are using query strings you will have to build your own URLs, rather than utilizing the URL helpers (and other helpers that generate URLs, like some of the form helpers) as these are designed to work with segment based URLs.

6.1.2 Controllers

Controllers are the heart of your application, as they determine how HTTP requests should be handled.

Page Contents

- Controllers
 - What is a Controller?

 - Remapping Method Calls
 - Processing Output
 - Private methods
 - Organizing Your Controllers into Sub-directories
 - Class Constructors
 - Reserved method names
 - That's it!

What is a Controller?

A Controller is simply a class file that is named in a way that can be associated with a URI.

Consider this URI:

```
example.com/index.php/blog/
```

In the above example, CodeIgniter would attempt to find a controller named Blog.php and load it.

When a controller's name matches the first segment of a URI, it will be loaded.

Let's try it: Hello World!

Let's create a simple controller so you can see it in action. Using your text editor, create a file called Blog.php, and put the following code in it:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        echo 'Hello World!';
    }

}
```

Then save the file to your *application/controllers/* directory.

: The file must be called 'Blog.php', with a capital 'B'.

Now visit the your site using a URL similar to this:

```
example.com/index.php/blog/
```

If you did it right, you should see:

Hello World!

: Class names must start with an uppercase letter.

This is valid:

```
<?php
class Blog extends CI_Controller {

}
```

This is **not** valid:

```
<?php
class blog extends CI_Controller {

}
```

Also, always make sure your controller extends the parent controller class so that it can inherit all its methods.

Methods

In the above example the method name is `index()`. The “index” method is always loaded by default if the **second segment** of the URI is empty. Another way to show your “Hello World” message would be this:

```
example.com/index.php/blog/index/
```

The second segment of the URI determines which method in the controller gets called.

Let’s try it. Add a new method to your controller:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        echo 'Hello World!';
    }

    public function comments()
    {
        echo 'Look at this!';
    }

}
```

Now load the following URL to see the comment method:

```
example.com/index.php/blog/comments/
```

You should see your new message.

Passing URI Segments to your methods

If your URI contains more than two segments they will be passed to your method as parameters.

For example, let’s say you have a URI like this:

```
example.com/index.php/products/shoes/sandals/123
```

Your method will be passed URI segments 3 and 4 (“sandals” and “123”):

```
<?php
class Products extends CI_Controller {

    public function shoes($sandals, $id)
    {
        echo $sandals;
        echo $id;
    }
}
```

: If you are using the *URI Routing* feature, the segments passed to your method will be the re-routed ones.

Defining a Default Controller

CodeIgniter can be told to load a default controller when a URI is not present, as will be the case when only your site root URL is requested. To specify a default controller, open your **application/config/routes.php** file and set this variable:

```
$route['default_controller'] = 'Blog';
```

Where Blog is the name of the controller class you want used. If you now load your main index.php file without specifying any URI segments you’ll see your Hello World message by default.

Remapping Method Calls

As noted above, the second segment of the URI typically determines which method in the controller gets called. CodeIgniter permits you to override this behavior through the use of the `_remap()` method:

```
public function _remap()
{
    // Some code here...
}
```

: If your controller contains a method named `_remap()`, it will **always** get called regardless of what your URI contains. It overrides the normal behavior in which the URI determines which method is called, allowing you to define your own method routing rules.

The overridden method call (typically the second segment of the URI) will be passed as a parameter to the `_remap()` method:

```
public function _remap($method)
{
    if ($method === 'some_method')
    {
        $this->$method();
    }
    else
    {
        $this->default_method();
    }
}
```

Any extra segments after the method name are passed into `_remap()` as an optional second parameter. This array can be used in combination with PHP's `call_user_func_array()` to emulate CodeIgniter's default behavior.

Example:

```
public function _remap($method, $params = array())
{
    $method = 'process_'. $method;
    if (method_exists($this, $method))
    {
        return call_user_func_array(array($this, $method), $params);
    }
    show_404();
}
```

Processing Output

CodeIgniter has an output class that takes care of sending your final rendered data to the web browser automatically. More information on this can be found in the *Views* and *Output Class* pages. In some cases, however, you might want to post-process the finalized data in some way and send it to the browser yourself. CodeIgniter permits you to add a method named `_output()` to your controller that will receive the finalized output data.

: If your controller contains a method named `_output()`, it will **always** be called by the output class instead of echoing the finalized data directly. The first parameter of the method will contain the finalized output.

Here is an example:

```
public function _output($output)
{
    echo $output;
}
```

: Please note that your `_output()` method will receive the data in its finalized state. Benchmark and memory usage data will be rendered, cache files written (if you have caching enabled), and headers will be sent (if you use that *feature*) before it is handed off to the `_output()` method. To have your controller's output cached properly, its `_output()` method can use:

```
if ($this->output->cache_expiration > 0)
{
    $this->output->_write_cache($output);
}
```

If you are using this feature the page execution timer and memory usage stats might not be perfectly accurate since they will not take into account any further processing you do. For an alternate way to control output *before* any of the final processing is done, please see the available methods in the *Output Library*.

Private methods

In some cases you may want certain methods hidden from public access. In order to achieve this, simply declare the method as being private or protected and it will not be served via a URL request. For example, if you were to have a method like this:

```
private function _utility()
{
```

```
// some code
}
```

Trying to access it via the URL, like this, will not work:

```
example.com/index.php/blog/_utility/
```

: Prefixing method names with an underscore will also prevent them from being called. This is a legacy feature that is left for backwards-compatibility.

Organizing Your Controllers into Sub-directories

If you are building a large application you might find it convenient to organize your controllers into sub-directories. CodeIgniter permits you to do this.

Simply create folders within your *application/controllers/* directory and place your controller classes within them.

: When using this feature the first segment of your URI must specify the folder. For example, let's say you have a controller located here:

```
application/controllers/products/Shoes.php
```

To call the above controller your URI will look something like this:

```
example.com/index.php/products/shoes/show/123
```

Each of your sub-directories may contain a default controller which will be called if the URL contains only the sub-folder. Simply name your default controller as specified in your *application/config/routes.php* file.

CodeIgniter also permits you to remap your URIs using its *URI Routing* feature.

Class Constructors

If you intend to use a constructor in any of your Controllers, you **MUST** place the following line of code in it:

```
parent::__construct();
```

The reason this line is necessary is because your local constructor will be overriding the one in the parent controller class so we need to manually call it.

Example:

```
<?php
class Blog extends CI_Controller {

    public function __construct()
    {
        parent::__construct();
        // Your own constructor code
    }
}
```

Constructors are useful if you need to set some default values, or run a default process when your class is instantiated. Constructors can't return a value, but they can do some default work.

Reserved method names

Since your controller classes will extend the main application controller you must be careful not to name your methods identically to the ones used by that class, otherwise your local functions will override them. See *Reserved Names* for a full list.

: You should also never have a method named identically to its class name. If you do, and there is no `__construct()` method in the same class, then your e.g. `Index::index()` method will be executed as a class constructor! This is a PHP4 backwards-compatibility feature.

That's it!

That, in a nutshell, is all there is to know about controllers.

6.1.3 Reserved Names

In order to help out, CodeIgniter uses a series of function, method, class and variable names in its operation. Because of this, some names cannot be used by a developer. Following is a list of reserved names that cannot be used.

Controller names

Since your controller classes will extend the main application controller you must be careful not to name your methods identically to the ones used by that class, otherwise your local methods will override them. The following is a list of reserved names. Do not name your controller any of these:

- Controller
- CI_Base
- _ci_initialize
- Default
- index

Functions

- `is_php()`
- `is_really_writable()`
- `load_class()`
- `is_loaded()`
- `get_config()`
- `config_item()`
- `show_error()`
- `show_404()`
- `log_message()`
- `set_status_header()`
- `get_mimes()`

- `html_escape()`
- `remove_invisible_characters()`
- `is_https()`
- `function_usable()`
- `get_instance()`
- `_exception_handler()`
- `_stringify_attributes()`

Variables

- `$config`
- `$db`
- `$lang`

Constants

- `ENVIRONMENT`
- `FCPATH`
- `SELF`
- `BASEPATH`
- `APPPATH`
- `VIEWPATH`
- `CI_VERSION`
- `FILE_READ_MODE`
- `FILE_WRITE_MODE`
- `DIR_READ_MODE`
- `DIR_WRITE_MODE`
- `FOPEN_READ`
- `FOPEN_READ_WRITE`
- `FOPEN_WRITE_CREATE_DESTRUCTIVE`
- `FOPEN_READ_WRITE_CREATE_DESTRUCTIVE`
- `FOPEN_WRITE_CREATE`
- `FOPEN_READ_WRITE_CREATE`
- `FOPEN_WRITE_CREATE_STRICT`
- `FOPEN_READ_WRITE_CREATE_STRICT`
- `EXIT_SUCCESS`
- `EXIT_ERROR`
- `EXIT_CONFIG`

- EXIT_UNKNOWN_FILE
- EXIT_UNKNOWN_CLASS
- EXIT_UNKNOWN_METHOD
- EXIT_USER_INPUT
- EXIT_DATABASE
- EXIT__AUTO_MIN
- EXIT__AUTO_MAX

6.1.4 Views

A view is simply a web page, or a page fragment, like a header, footer, sidebar, etc. In fact, views can flexibly be embedded within other views (within other views, etc., etc.) if you need this type of hierarchy.

Views are never called directly, they must be loaded by a *controller*. Remember that in an MVC framework, the Controller acts as the traffic cop, so it is responsible for fetching a particular view. If you have not read the *Controllers* page you should do so before continuing.

Using the example controller you created in the *controller* page, let's add a view to it.

Creating a View

Using your text editor, create a file called `blogview.php`, and put this in it:

```
<html>
<head>
    <title>My Blog</title>
</head>
<body>
    <h1>Welcome to my Blog!</h1>
</body>
</html>
```

Then save the file in your *application/views/* directory.

Loading a View

To load a particular view file you will use the following method:

```
$this->load->view('name');
```

Where name is the name of your view file.

: The `.php` file extension does not need to be specified unless you use something other than `.php`.

Now, open the controller file you made earlier called `Blog.php`, and replace the `echo` statement with the view loading method:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
```

```

        $this->load->view('blogview');
    }
}

```

If you visit your site using the URL you did earlier you should see your new view. The URL was similar to this:

`example.com/index.php/blog/`

Loading multiple views

CodeIgniter will intelligently handle multiple calls to `$this->load->view()` from within a controller. If more than one call happens they will be appended together. For example, you may wish to have a header view, a menu view, a content view, and a footer view. That might look something like this:

```

<?php

class Page extends CI_Controller {

    public function index()
    {
        $data['page_title'] = 'Your title';
        $this->load->view('header');
        $this->load->view('menu');
        $this->load->view('content', $data);
        $this->load->view('footer');
    }

}

```

In the example above, we are using “dynamically added data”, which you will see below.

Storing Views within Sub-directories

Your view files can also be stored within sub-directories if you prefer that type of organization. When doing so you will need to include the directory name loading the view. Example:

```

$this->load->view('directory_name/file_name');

```

Adding Dynamic Data to the View

Data is passed from the controller to the view by way of an **array** or an **object** in the second parameter of the view loading method. Here is an example using an array:

```

$data = array(
    'title' => 'My Title',
    'heading' => 'My Heading',
    'message' => 'My Message'
);

$this->load->view('blogview', $data);

```

And here’s an example using an object:

```

$data = new Someclass();
$this->load->view('blogview', $data);

```

: If you use an object, the class variables will be turned into array elements.

Let's try it with your controller file. Open it add this code:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        $data['title'] = "My Real Title";
        $data['heading'] = "My Real Heading";

        $this->load->view('blogview', $data);
    }
}
```

Now open your view file and change the text to variables that correspond to the array keys in your data:

```
<html>
<head>
    <title><?php echo $title;?></title>
</head>
<body>
    <h1><?php echo $heading;?></h1>
</body>
</html>
```

Then load the page at the URL you've been using and you should see the variables replaced.

Creating Loops

The data array you pass to your view files is not limited to simple variables. You can pass multi dimensional arrays, which can be looped to generate multiple rows. For example, if you pull data from your database it will typically be in the form of a multi-dimensional array.

Here's a simple example. Add this to your controller:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        $data['todo_list'] = array('Clean House', 'Call Mom', 'Run Errands');

        $data['title'] = "My Real Title";
        $data['heading'] = "My Real Heading";

        $this->load->view('blogview', $data);
    }
}
```

Now open your view file and create a loop:

```
<html>
<head>
    <title><?php echo $title;?></title>
</head>
<body>
```

```

<h1><?php echo $heading;?></h1>

<h3>My Todo List</h3>

<ul>
<?php foreach ($todo_list as $item):?>

    <li><?php echo $item;?></li>

<?php endforeach;?>
</ul>

</body>
</html>

```

: You'll notice that in the example above we are using PHP's alternative syntax. If you are not familiar with it you can read about it *here*.

Returning views as data

There is a third **optional** parameter lets you change the behavior of the method so that it returns data as a string rather than sending it to your browser. This can be useful if you want to process the data in some way. If you set the parameter to TRUE (boolean) it will return data. The default behavior is false, which sends it to your browser. Remember to assign it to a variable if you want the data returned:

```
$string = $this->load->view('myfile', '', TRUE);
```

6.1.5 Models

Models are **optionally** available for those who want to use a more traditional MVC approach.

Page Contents

- Models
 - What is a Model?
 - Anatomy of a Model
 - Loading a Model
 - Auto-loading Models
 - Connecting to your Database

What is a Model?

Models are PHP classes that are designed to work with information in your database. For example, let's say you use CodeIgniter to manage a blog. You might have a model class that contains functions to insert, update, and retrieve your blog data. Here is an example of what such a model class might look like:

```

class Blog_model extends CI_Model {

    public $title;
    public $content;
    public $date;

```

```
public function __construct()
{
    // Call the CI_Model constructor
    parent::__construct();
}

public function get_last_ten_entries()
{
    $query = $this->db->get('entries', 10);
    return $query->result();
}

public function insert_entry()
{
    $this->title    = $_POST['title']; // please read the below note
    $this->content  = $_POST['content'];
    $this->date     = time();

    $this->db->insert('entries', $this);
}

public function update_entry()
{
    $this->title    = $_POST['title'];
    $this->content  = $_POST['content'];
    $this->date     = time();

    $this->db->update('entries', $this, array('id' => $_POST['id']));
}
}
```

: The methods in the above example use the *Query Builder* database methods.

: For the sake of simplicity in this example we're using `$_POST` directly. This is generally bad practice, and a more common approach would be to use the *Input Library* `$this->input->post('title')`.

Anatomy of a Model

Model classes are stored in your **application/models/** directory. They can be nested within sub-directories if you want this type of organization.

The basic prototype for a model class is this:

```
class Model_name extends CI_Model {

    public function __construct()
    {
        parent::__construct();
    }

}
```

Where **Model_name** is the name of your class. Class names **must** have the first letter capitalized with the rest of the name lowercase. Make sure your class extends the base Model class.

The file name must match the class name. For example, if this is your class:

```
class User_model extends CI_Model {

    public function __construct()
    {
        parent::__construct();
    }

}
```

Your file will be this:

```
application/models/User_model.php
```

Loading a Model

Your models will typically be loaded and called from within your *controller* methods. To load a model you will use the following method:

```
$this->load->model('model_name');
```

If your model is located in a sub-directory, include the relative path from your models directory. For example, if you have a model located at *application/models/blog/Queries.php* you'll load it using:

```
$this->load->model('blog/queries');
```

Once loaded, you will access your model methods using an object with the same name as your class:

```
$this->load->model('model_name');
```

```
$this->model_name->method();
```

If you would like your model assigned to a different object name you can specify it via the second parameter of the loading method:

```
$this->load->model('model_name', 'foobar');
```

```
$this->foobar->method();
```

Here is an example of a controller, that loads a model, then serves a view:

```
class Blog_controller extends CI_Controller {

    public function blog()
    {
        $this->load->model('blog');

        $data['query'] = $this->Blog->get_last_ten_entries();

        $this->load->view('blog', $data);
    }

}
```

Auto-loading Models

If you find that you need a particular model globally throughout your application, you can tell CodeIgniter to auto-load it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the

model to the autoload array.

Connecting to your Database

When a model is loaded it does **NOT** connect automatically to your database. The following options for connecting are available to you:

- You can connect using the standard database methods *described here*, either from within your Controller class or your Model class.
- You can tell the model loading method to auto-connect by passing TRUE (boolean) via the third parameter, and connectivity settings, as defined in your database config file will be used:

```
$this->load->model('model_name', '', TRUE);
```

- You can manually pass database connectivity settings via the third parameter:

```
$config['hostname'] = 'localhost';
$config['username'] = 'myusername';
$config['password'] = 'mypassword';
$config['database'] = 'mydatabase';
$config['dbdriver'] = 'mysqli';
$config['dbprefix'] = '';
$config['pconnect'] = FALSE;
$config['db_debug'] = TRUE;

$this->load->model('model_name', '', $config);
```

6.1.6 Helper Functions

Helpers, as the name suggests, help you with tasks. Each helper file is simply a collection of functions in a particular category. There are **URL Helpers**, that assist in creating links, there are Form Helpers that help you create form elements, **Text Helpers** perform various text formatting routines, **Cookie Helpers** set and read cookies, File Helpers help you deal with files, etc.

Unlike most other systems in CodeIgniter, Helpers are not written in an Object Oriented format. They are simple, procedural functions. Each helper function performs one specific task, with no dependence on other functions.

CodeIgniter does not load Helper Files by default, so the first step in using a Helper is to load it. Once loaded, it becomes globally available in your *controller* and *views*.

Helpers are typically stored in your **system/helpers**, or **application/helpers directory**. CodeIgniter will look first in your **application/helpers directory**. If the directory does not exist or the specified helper is not located there CI will instead look in your global *system/helpers/* directory.

Loading a Helper

Loading a helper file is quite simple using the following method:

```
$this->load->helper('name');
```

Where **name** is the file name of the helper, without the .php file extension or the “helper” part.

For example, to load the **URL Helper** file, which is named **url_helper.php**, you would do this:

```
$this->load->helper('url');
```

A helper can be loaded anywhere within your controller methods (or even within your View files, although that's not a good practice), as long as you load it before you use it. You can load your helpers in your controller constructor so that they become available automatically in any function, or you can load a helper in a specific function that needs it.

: The Helper loading method above does not return a value, so don't try to assign it to a variable. Just use it as shown.

Loading Multiple Helpers

If you need to load more than one helper you can specify them in an array, like this:

```
$this->load->helper(
    array('helper1', 'helper2', 'helper3')
);
```

Auto-loading Helpers

If you find that you need a particular helper globally throughout your application, you can tell CodeIgniter to auto-load it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the helper to the autoload array.

Using a Helper

Once you've loaded the Helper File containing the function you intend to use, you'll call it the way you would a standard PHP function.

For example, to create a link using the `anchor()` function in one of your view files you would do this:

```
<?php echo anchor('blog/comments', 'Click Here');?>
```

Where "Click Here" is the name of the link, and "blog/comments" is the URI to the controller/method you wish to link to.

"Extending" Helpers

To "extend" Helpers, create a file in your **application/helpers/** folder with an identical name to the existing Helper, but prefixed with **MY_** (this item is configurable. See below.).

If all you need to do is add some functionality to an existing helper - perhaps add a function or two, or change how a particular helper function operates - then it's overkill to replace the entire helper with your version. In this case it's better to simply "extend" the Helper.

: The term "extend" is used loosely since Helper functions are procedural and discrete and cannot be extended in the traditional programmatic sense. Under the hood, this gives you the ability to add to or to replace the functions a Helper provides.

For example, to extend the native **Array Helper** you'll create a file named **application/helpers/MY_array_helper.php**, and add or override functions:

```
// any_in_array() is not in the Array Helper, so it defines a new function
function any_in_array($needle, $haystack)
{
    $needle = is_array($needle) ? $needle : array($needle);
```

```
        foreach ($needle as $item)
        {
            if (in_array($item, $haystack))
            {
                return TRUE;
            }
        }

        return FALSE;
    }

    // random_element() is included in Array Helper, so it overrides the native function
    function random_element($array)
    {
        shuffle($array);
        return array_pop($array);
    }
}
```

Setting Your Own Prefix

The filename prefix for “extending” Helpers is the same used to extend libraries and core classes. To set your own prefix, open your **application/config/config.php** file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with **CI_** so DO NOT use that as your prefix.

Now What?

In the Table of Contents you’ll find a list of all the available Helper Files. Browse each one to see what they do.

6.1.7 Using CodeIgniter Libraries

All of the available libraries are located in your *system/libraries/* directory. In most cases, to use one of these classes involves initializing it within a *controller* using the following initialization method:

```
$this->load->library('class_name');
```

Where ‘class_name’ is the name of the class you want to invoke. For example, to load the *Form Validation Library* you would do this:

```
$this->load->library('form_validation');
```

Once initialized you can use it as indicated in the user guide page corresponding to that class.

Additionally, multiple libraries can be loaded at the same time by passing an array of libraries to the load method.

Example:

```
$this->load->library(array('email', 'table'));
```

Creating Your Own Libraries

Please read the section of the user guide that discusses how to *create your own libraries*.

6.1.8 Creating Libraries

When we use the term “Libraries” we are normally referring to the classes that are located in the libraries directory and described in the Class Reference of this user guide. In this case, however, we will instead describe how you can create your own libraries within your *application/libraries* directory in order to maintain separation between your local resources and the global framework resources.

As an added bonus, CodeIgniter permits your libraries to extend native classes if you simply need to add some functionality to an existing library. Or you can even replace native libraries just by placing identically named versions in your *application/libraries* directory.

In summary:

- You can create entirely new libraries.
- You can extend native libraries.
- You can replace native libraries.

The page below explains these three concepts in detail.

: The Database classes can not be extended or replaced with your own classes. All other classes are able to be replaced/extended.

Storage

Your library classes should be placed within your *application/libraries* directory, as this is where CodeIgniter will look for them when they are initialized.

Naming Conventions

- File names must be capitalized. For example: Myclass.php
- Class declarations must be capitalized. For example: class Myclass
- Class names and file names must match.

The Class File

Classes should have this basic prototype:

```
<?php if ( ! defined('BASEPATH')) exit('No direct script access allowed');

class Someclass {

    public function some_method()
    {
    }

}

/* End of file Someclass.php */
```

: We are using the name Someclass purely as an example.

Using Your Class

From within any of your *Controller* methods you can initialize your class using the standard:

```
$this->load->library('someclass');
```

Where *someclass* is the file name, without the ".php" file extension. You can submit the file name capitalized or lower case. CodeIgniter doesn't care.

Once loaded you can access your class using the lower case version:

```
$this->someclass->some_method(); // Object instances will always be lower case
```

Passing Parameters When Initializing Your Class

In the library loading method you can dynamically pass data as an array via the second parameter and it will be passed to your class constructor:

```
$params = array('type' => 'large', 'color' => 'red');  
  
$this->load->library('someclass', $params);
```

If you use this feature you must set up your class constructor to expect data:

```
<?php defined('BASEPATH') OR exit('No direct script access allowed');  
  
class Someclass {  
  
    public function __construct($params)  
    {  
        // Do something with $params  
    }  
}
```

You can also pass parameters stored in a config file. Simply create a config file named identically to the class file name and store it in your *application/config/* directory. Note that if you dynamically pass parameters as described above, the config file option will not be available.

Utilizing CodeIgniter Resources within Your Library

To access CodeIgniter's native resources within your library use the `get_instance()` method. This method returns the CodeIgniter super object.

Normally from within your controller methods you will call any of the available CodeIgniter methods using the `$this` construct:

```
$this->load->helper('url');  
$this->load->library('session');  
$this->config->item('base_url');  
// etc.
```

`$this`, however, only works directly within your controllers, your models, or your views. If you would like to use CodeIgniter's classes from within your own custom classes you can do so as follows:

First, assign the CodeIgniter object to a variable:

```
$CI =& get_instance();
```

Once you've assigned the object to a variable, you'll use that variable *instead* of `$this`:

```
$CI =& get_instance();

$CI->load->helper('url');
$CI->load->library('session');
$CI->config->item('base_url');
// etc.
```

: You'll notice that the above `get_instance()` function is being passed by reference:

```
$CI =& get_instance();
```

This is very important. Assigning by reference allows you to use the original CodeIgniter object rather than creating a copy of it.

However, since a library is a class, it would be better if you take full advantage of the OOP principles. So, in order to be able to use the CodeIgniter super-object in all of the class methods, you're encouraged to assign it to a property instead:

```
class Example_library {

    protected $CI;

    // We'll use a constructor, as you can't directly call a function
    // from a property definition.
    public function __construct()
    {
        // Assign the CodeIgniter super-object
        $this->CI =& get_instance();
    }

    public function foo()
    {
        $this->CI->load->helper('url');
        redirect();
    }

    public function bar()
    {
        echo $this->CI->config_item('base_url');
    }

}
```

Replacing Native Libraries with Your Versions

Simply by naming your class files identically to a native library will cause CodeIgniter to use it instead of the native one. To use this feature you must name the file and the class declaration exactly the same as the native library. For example, to replace the native Email library you'll create a file named *application/libraries/Email.php*, and declare your class with:

```
class CI_Email {

}
```

Note that most native classes are prefixed with `CI_`.

To load your library you'll see the standard loading method:

```
$this->load->library('email');
```

: At this time the Database classes can not be replaced with your own versions.

Extending Native Libraries

If all you need to do is add some functionality to an existing library - perhaps add a method or two - then it's overkill to replace the entire library with your version. In this case it's better to simply extend the class. Extending a class is nearly identical to replacing a class with a couple exceptions:

- The class declaration must extend the parent class.
- Your new class name and filename must be prefixed with MY_ (this item is configurable. See below.).

For example, to extend the native Email class you'll create a file named *application/libraries/MY_Email.php*, and declare your class with:

```
class MY_Email extends CI_Email {  
  
}
```

If you need to use a constructor in your class make sure you extend the parent constructor:

```
class MY_Email extends CI_Email {  
  
    public function __construct($config = array())  
    {  
        parent::__construct($config);  
    }  
  
}
```

: Not all of the libraries have the same (or any) parameters in their constructor. Take a look at the library that you're extending first to see how it should be implemented.

Loading Your Sub-class

To load your sub-class you'll use the standard syntax normally used. DO NOT include your prefix. For example, to load the example above, which extends the Email class, you will use:

```
$this->load->library('email');
```

Once loaded you will use the class variable as you normally would for the class you are extending. In the case of the email class all calls will use:

```
$this->email->some_method();
```

Setting Your Own Prefix

To set your own sub-class prefix, open your *application/config/config.php* file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with `CI_` so DO NOT use that as your prefix.

6.1.9 Using CodeIgniter Drivers

Drivers are a special type of Library that has a parent class and any number of potential child classes. Child classes have access to the parent class, but not their siblings. Drivers provide an elegant syntax in your *controllers* for libraries that benefit from or require being broken down into discrete classes.

Drivers are found in the *system/libraries/* directory, in their own sub-directory which is identically named to the parent library class. Also inside that directory is a subdirectory named *drivers*, which contains all of the possible child class files.

To use a driver you will initialize it within a controller using the following initialization method:

```
$this->load->driver('class_name');
```

Where class name is the name of the driver class you want to invoke. For example, to load a driver named “Some_parent” you would do this:

```
$this->load->driver('some_parent');
```

Methods of that class can then be invoked with:

```
$this->some_parent->some_method();
```

The child classes, the drivers themselves, can then be called directly through the parent class, without initializing them:

```
$this->some_parent->child_one->some_method();  
$this->some_parent->child_two->another_method();
```

Creating Your Own Drivers

Please read the section of the user guide that discusses how to *create your own drivers*.

6.1.10 Creating Drivers

Driver Directory and File Structure

Sample driver directory and file structure layout:

- /application/libraries/Driver_name
 - Driver_name.php
 - drivers
 - * Driver_name_subclass_1.php
 - * Driver_name_subclass_2.php
 - * Driver_name_subclass_3.php

: In order to maintain compatibility on case-sensitive file systems, the *Driver_name* directory must be named in the format returned by `ucfirst()`.

6.1.11 Creating Core System Classes

Every time CodeIgniter runs there are several base classes that are initialized automatically as part of the core framework. It is possible, however, to swap any of the core system classes with your own versions or even extend the core versions.

Most users will never have any need to do this, but the option to replace or extend them does exist for those who would like to significantly alter the CodeIgniter core.

: Messing with a core system class has a lot of implications, so make sure you know what you are doing before attempting it.

System Class List

The following is a list of the core system files that are invoked every time CodeIgniter runs:

- Benchmark
- Config
- Controller
- Exceptions
- Hooks
- Input
- Language
- Loader
- Log
- Output
- Router
- Security
- URI
- Utf8

Replacing Core Classes

To use one of your own system classes instead of a default one simply place your version inside your local *application/core/* directory:

```
application/core/some_class.php
```

If this directory does not exist you can create it.

Any file named identically to one from the list above will be used instead of the one normally used.

Please note that your class must use CI as a prefix. For example, if your file is named Input.php the class will be named:

```
class CI_Input {  
  
}
```

Extending Core Class

If all you need to do is add some functionality to an existing library - perhaps add a method or two - then it's overkill to replace the entire library with your version. In this case it's better to simply extend the class. Extending a class is nearly identical to replacing a class with a couple exceptions:

- The class declaration must extend the parent class.
- Your new class name and filename must be prefixed with MY_ (this item is configurable. See below.).

For example, to extend the native Input class you'll create a file named `application/core/MY_Input.php`, and declare your class with:

```
class MY_Input extends CI_Input {
}
```

: If you need to use a constructor in your class make sure you extend the parent constructor:

```
class MY_Input extends CI_Input {
    public function __construct()
    {
        parent::__construct();
    }
}
```

Tip: Any functions in your class that are named identically to the methods in the parent class will be used instead of the native ones (this is known as “method overriding”). This allows you to substantially alter the CodeIgniter core.

If you are extending the Controller core class, then be sure to extend your new class in your application controller's constructors.

```
class Welcome extends MY_Controller {
    public function __construct()
    {
        parent::__construct();
    }

    public function index()
    {
        $this->load->view('welcome_message');
    }
}
```

Setting Your Own Prefix

To set your own sub-class prefix, open your `application/config/config.php` file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with CI_ so DO NOT use that as your prefix.

6.1.12 Creating Ancillary Classes

In some cases you may want to develop classes that exist apart from your controllers but have the ability to utilize all of CodeIgniter's resources. This is easily possible as you'll see.

`get_instance()`

`get_instance()`

object of class `CI_Controller`

Any class that you instantiate within your controller methods can access CodeIgniter's native resources simply by using the `get_instance()` function. This function returns the main CodeIgniter object.

Normally, to call any of the available CodeIgniter methods requires you to use the `$this` construct:

```
$this->load->helper('url');
$this->load->library('session');
$this->config->item('base_url');
// etc.
```

`$this`, however, only works within your controllers, your models, or your views. If you would like to use CodeIgniter's classes from within your own custom classes you can do so as follows:

First, assign the CodeIgniter object to a variable:

```
$CI =& get_instance();
```

Once you've assigned the object to a variable, you'll use that variable *instead* of `$this`:

```
$CI =& get_instance();

$CI->load->helper('url');
$CI->load->library('session');
$CI->config->item('base_url');
// etc.
```

: You'll notice that the above `get_instance()` function is being passed by reference:

```
$CI =& get_instance();
```

This is very important. Assigning by reference allows you to use the original CodeIgniter object rather than creating a copy of it.

Furthermore, if you'll be using `get_instance()` inside another class, then it would be better if you assign it to a property. This way, you won't need to call `get_instance()` in every single method.

Example:

```
class Example {

    protected $CI;

    // We'll use a constructor, as you can't directly call a function
    // from a property definition.
    public function __construct()
    {
        // Assign the CodeIgniter super-object
        $this->CI =& get_instance();
    }
}
```

```

    }

    public function foo()
    {
        $this->CI->load->helper('url');
        redirect();
    }

    public function bar()
    {
        $this->CI->config_item('base_url');
    }
}

```

In the above example, both methods `foo()` and `bar()` will work after you instantiate the `Example` class, without the need to call `get_instance()` in each of them.

6.1.13 Hooks - Extending the Framework Core

CodeIgniter's Hooks feature provides a means to tap into and modify the inner workings of the framework without hacking the core files. When CodeIgniter runs it follows a specific execution process, diagramed in the *Application Flow* page. There may be instances, however, where you'd like to cause some action to take place at a particular stage in the execution process. For example, you might want to run a script right before your controllers get loaded, or right after, or you might want to trigger one of your own scripts in some other location.

Enabling Hooks

The hooks feature can be globally enabled/disabled by setting the following item in the **application/config/config.php** file:

```
$config['enable_hooks'] = TRUE;
```

Defining a Hook

Hooks are defined in **application/config/hooks.php** file. Each hook is specified as an array with this prototype:

```

$hook['pre_controller'] = array(
    'class'    => 'MyClass',
    'function' => 'Myfunction',
    'filename' => 'Myclass.php',
    'filepath' => 'hooks',
    'params'   => array('beer', 'wine', 'snacks')
);

```

Notes:

The array index correlates to the name of the particular hook point you want to use. In the above example the hook point is `pre_controller`. A list of hook points is found below. The following items should be defined in your associative hook array:

- **class** The name of the class you wish to invoke. If you prefer to use a procedural function instead of a class, leave this item blank.
- **function** The function (or method) name you wish to call.

- **filename** The file name containing your class/function.
- **filepath** The name of the directory containing your script. Note: Your script must be located in a directory *INSIDE* your *application/* directory, so the file path is relative to that directory. For example, if your script is located in *application/hooks/*, you will simply use 'hooks' as your filepath. If your script is located in *application/hooks/utilities/* you will use 'hooks/utilities' as your filepath. No trailing slash.
- **params** Any parameters you wish to pass to your script. This item is optional.

Multiple Calls to the Same Hook

If want to use the same hook point with more then one script, simply make your array declaration multi-dimensional, like this:

```
$hook['pre_controller'][] = array(
    'class'      => 'MyClass',
    'function'   => 'MyMethod',
    'filename'   => 'Myclass.php',
    'filepath'   => 'hooks',
    'params'     => array('beer', 'wine', 'snacks')
);

$hook['pre_controller'][] = array(
    'class'      => 'MyOtherClass',
    'function'   => 'MyOtherMethod',
    'filename'   => 'Myotherclass.php',
    'filepath'   => 'hooks',
    'params'     => array('red', 'yellow', 'blue')
);
```

Notice the brackets after each array index:

```
$hook['pre_controller'] []
```

This permits you to have the same hook point with multiple scripts. The order you define your array will be the execution order.

Hook Points

The following is a list of available hook points.

- **pre_system** Called very early during system execution. Only the benchmark and hooks class have been loaded at this point. No routing or other processes have happened.
- **pre_controller** Called immediately prior to any of your controllers being called. All base classes, routing, and security checks have been done.
- **post_controller_constructor** Called immediately after your controller is instantiated, but prior to any method calls happening.
- **post_controller** Called immediately after your controller is fully executed.
- **display_override** Overrides the `_display()` method, used to send the finalized page to the web browser at the end of system execution. This permits you to use your own display methodology. Note that you will need to reference the CI superobject with `$this->CI =& get_instance()` and then the finalized data will be available by calling `$this->CI->output->get_output()`.
- **cache_override** Enables you to call your own method instead of the `_display_cache()` method in the *Output Library*. This permits you to use your own cache display mechanism.

- **post_system** Called after the final rendered page is sent to the browser, at the end of system execution after the finalized data is sent to the browser.

6.1.14 Auto-loading Resources

CodeIgniter comes with an “Auto-load” feature that permits libraries, helpers, and models to be initialized automatically every time the system runs. If you need certain resources globally throughout your application you should consider auto-loading them for convenience.

The following items can be loaded automatically:

- Classes found in the *libraries/* directory
- Helper files found in the *helpers/* directory
- Custom config files found in the *config/* directory
- Language files found in the *system/language/* directory
- Models found in the *models/* folder

To autoload resources, open the **application/config/autoload.php** file and add the item you want loaded to the autoload array. You’ll find instructions in that file corresponding to each type of item.

: Do not include the file extension (.php) when adding items to the autoload array.

6.1.15 Common Functions

CodeIgniter uses a few functions for its operation that are globally defined, and are available to you at any point. These do not require loading any libraries or helpers.

is_php()

is_php (\$version = '5.3.0')

- **\$version** (*string*) – Version number

bool

Determines if the PHP version being used is greater than the supplied version number.

Example:

```
if (is_php('5.3'))
{
    $str = quoted_printable_encode($str);
}
```

Returns boolean TRUE if the installed version of PHP is equal to or greater than the supplied version number. Returns FALSE if the installed version of PHP is lower than the supplied version number.

is_really_writable()

is_really_writable (\$file)

- **\$file** (*string*) – File path

bool

`is_writable()` returns TRUE on Windows servers when you really can't write to the file as the OS reports to PHP as FALSE only if the read-only attribute is marked.

This function determines if a file is actually writable by attempting to write to it first. Generally only recommended on platforms where this information may be unreliable.

Example:

```
if (is_really_writable('file.txt'))
{
    echo "I could write to this if I wanted to";
}
else
{
    echo "File is not writable";
}
```

config_item()

config_item (*\$key*)

- **\$key** (*string*) – Config item key

mixed

The *Config Library* is the preferred way of accessing configuration information, however `config_item()` can be used to retrieve single keys. See *Config Library* documentation for more information.

show_error()

show_error (*\$message*, *\$status_code*, *\$heading* = 'An Error Was Encountered')

- **\$message** (*mixed*) – Error message
- **\$status_code** (*int*) – HTTP Response status code
- **\$heading** (*string*) – Error page heading

void

This function calls `CI_Exception::show_error()`. For more info, please see the *Error Handling* documentation.

show_404()

show_404 (*\$page* = '', *\$log_error* = TRUE)

- **\$page** (*string*) – URI string
- **\$log_error** (*bool*) – Whether to log the error

void

This function calls `CI_Exception::show_404()`. For more info, please see the *Error Handling* documentation.

log_message()

log_message (*\$level*, *\$message*)

- **\$level** (*string*) – Log level: ‘error’, ‘debug’ or ‘info’
- **\$message** (*string*) – Message to log

void

This function is an alias for `CI_Log::write_log()`. For more info, please see the *Error Handling* documentation.

set_status_header()

set_status_header (*\$code*, *\$text* = ‘’)

- **\$code** (*int*) – HTTP Reponse status code
- **\$text** (*string*) – A custom message to set with the status code

void

Permits you to manually set a server status header. Example:

```
set_status_header(401);
// Sets the header as: Unauthorized
```

See [here](#) for a full list of headers.

remove_invisible_characters()

remove_invisible_characters (*\$str*, *\$url_encoded* = *TRUE*)

- **\$str** (*string*) – Input string
- **\$url_encoded** (*bool*) – Whether to remove URL-encoded characters as well

string

This function prevents inserting NULL characters between ASCII characters, like `Java\0script`.

Example:

```
remove_invisible_characters('Java\0script');
// Returns: 'Javascript'
```

html_escape()

html_escape (*\$var*)

- **\$var** (*mixed*) – Variable to escape (string or array)

mixed

This function acts as an alias for PHP's native `htmlspecialchars()` function, with the advantage of being able to accept an array of strings.

It is useful in preventing Cross Site Scripting (XSS).

get_mimes()

get_mimes()

array

This function returns a *reference* to the MIMes array from *application/config/mimes.php*.

is_https()

is_https()

bool

Returns TRUE if a secure (HTTPS) connection is used and FALSE in any other case (including non-HTTP requests).

is_cli()

is_cli()

bool

Returns TRUE if the application is run through the command line and FALSE if not.

: This function checks both if the `PHP_SAPI` value is 'cli' or if the `STDIN` constant is defined.

function_usable()

function_usable (*\$function_name*)

- **\$function_name** (*string*) – Function name

bool

Returns TRUE if a function exists and is usable, FALSE otherwise.

This function runs a `function_exists()` check and if the *Suhosin extension* <<http://www.hardened-php.net/suhosin/>> is loaded, checks if it doesn't disable the function being checked.

It is useful if you want to check for the availability of functions such as `eval()` and `exec()`, which are dangerous and might be disabled on servers with highly restrictive security policies.

6.1.16 URI Routing

Typically there is a one-to-one relationship between a URL string and its corresponding controller class/method. The segments in a URI normally follow this pattern:

```
example.com/class/function/id/
```

In some instances, however, you may want to remap this relationship so that a different class/method can be called instead of the one corresponding to the URL.

For example, let's say you want your URLs to have this prototype:

```
example.com/product/1/  
example.com/product/2/  
example.com/product/3/  
example.com/product/4/
```

Normally the second segment of the URL is reserved for the method name, but in the example above it instead has a product ID. To overcome this, CodeIgniter allows you to remap the URI handler.

Setting your own routing rules

Routing rules are defined in your *application/config/routes.php* file. In it you'll see an array called `$route` that permits you to specify your own routing criteria. Routes can either be specified using wildcards or Regular Expressions.

Wildcards

A typical wildcard route might look something like this:

```
$route['product/:num'] = 'catalog/product_lookup';
```

In a route, the array key contains the URI to be matched, while the array value contains the destination it should be re-routed to. In the above example, if the literal word “product” is found in the first segment of the URL, and a number is found in the second segment, the “catalog” class and the “product_lookup” method are instead used.

You can match literal values or you can use two wildcard types:

(:num) will match a segment containing only numbers. **(:any)** will match a segment containing any character (except for `'`, which is the segment delimiter).

: Wildcards are actually aliases for regular expressions, with **:any** being translated to `[^/]+` and **:num** to `[0-9]+`, respectively.

: Routes will run in the order they are defined. Higher routes will always take precedence over lower ones.

: Route rules are not filters! Setting a rule of e.g. `'foo/bar/(num)'` will not prevent controller *Foo* and method *bar* to be called with a non-numeric value if that is a valid route.

Examples

Here are a few routing examples:

```
$route['journals'] = 'blogs';
```

A URL containing the word “journals” in the first segment will be remapped to the “blogs” class.

```
$route['blog/joe'] = 'blogs/users/34';
```

A URL containing the segments `blog/joe` will be remapped to the “blogs” class and the “users” method. The ID will be set to “34”.

```
$route['product/(:any)'] = 'catalog/product_lookup';
```

A URL with “product” as the first segment, and anything in the second will be remapped to the “catalog” class and the “product_lookup” method.

```
$route['product/(:num)'] = 'catalog/product_lookup_by_id/$1';
```

A URL with “product” as the first segment, and a number in the second will be remapped to the “catalog” class and the “product_lookup_by_id” method passing in the match as a variable to the method.

: Do not use leading/trailing slashes.

Regular Expressions

If you prefer you can use regular expressions to define your routing rules. Any valid regular expression is allowed, as are back-references.

: If you use back-references you must use the dollar syntax rather than the double backslash syntax.

A typical RegEx route might look something like this:

```
$route['products/([a-z]+)/(\d+)'] = '$1/id_$2';
```

In the above example, a URI similar to `products/shirts/123` would instead call the “shirts” controller class and the “id_123” method.

With regular expressions, you can also catch a segment containing a forward slash (/), which would usually represent the delimiter between multiple segments. For example, if a user accesses a password protected area of your web application and you wish to be able to redirect them back to the same page after they log in, you may find this example useful:

```
$route['login/(.)'] = 'auth/login/$1';
```

That will call the “auth” controller class and its `login()` method, passing everything contained in the URI after `login/` as a parameter.

For those of you who don’t know regular expressions and want to learn more about them, *regular-expressions.info* <<http://www.regular-expressions.info/>> might be a good starting point.

: You can also mix and match wildcards with regular expressions.

Callbacks

If you are using PHP >= 5.3 you can use callbacks in place of the normal routing rules to process the back-references. Example:

```
$route['products/([a-zA-Z]+)/edit/(\d+)'] = function ($product_type, $id)
{
    return 'catalog/product_edit/' . strtolower($product_type) . '/' . $id;
};
```

Using HTTP verbs in routes

It is possible to use HTTP verbs (request method) to define your routing rules. This is particularly useful when building RESTful applications. You can use standard HTTP verbs (GET, PUT, POST, DELETE, PATCH) or a custom one such (e.g. PURGE). HTTP verb rules are case-insensitive. All you need to do is to add the verb as an array key to your route. Example:

```
$route['products']['put'] = 'product/insert';
```

In the above example, a PUT request to URI “products” would call the `Product::insert()` controller method.

```
$route['products/(:num)']['DELETE'] = 'product/delete/$1';
```

A DELETE request to URL with “products” as first the segment and a number in the second will be mapped to the `Product::delete()` method, passing the numeric value as the first parameter.

Using HTTP verbs is of course, optional.

Reserved Routes

There are three reserved routes:

```
$route['default_controller'] = 'welcome';
```

This route indicates which controller class should be loaded if the URI contains no data, which will be the case when people load your root URL. In the above example, the “welcome” class would be loaded. You are encouraged to always have a default route otherwise a 404 page will appear by default.

```
$route['404_override'] = '';
```

This route indicates which controller class should be loaded if the requested controller is not found. It will override the default 404 error page. It won't affect to the `show_404()` function, which will continue loading the default *error_404.php* file at *application/views/errors/error_404.php*.

```
$route['translate_uri_dashes'] = FALSE;
```

As evident by the boolean value, this is not exactly a route. This option enables you to automatically replace dashes ('-') with underscores in the controller and method URI segments, thus saving you additional route entries if you need to do that. This is required, because the dash isn't a valid class or method name character and would cause a fatal error if you try to use it.

: The reserved routes must come before any wildcard or regular expression routes.

6.1.17 Error Handling

CodeIgniter lets you build error reporting into your applications using the functions described below. In addition, it has an error logging class that permits error and debugging messages to be saved as text files.

: By default, CodeIgniter displays all PHP errors. You might wish to change this behavior once your development is complete. You'll find the `error_reporting()` function located at the top of your main *index.php* file. Disabling error reporting will NOT prevent log files from being written if there are errors.

Unlike most systems in CodeIgniter, the error functions are simple procedural interfaces that are available globally throughout the application. This approach permits error messages to get triggered without having to worry about class/function scoping.

CodeIgniter also returns a status code whenever a portion of the core calls `exit()`. This exit status code is separate from the HTTP status code, and serves as a notice to other processes that may be watching of whether the script completed successfully, or if not, what kind of problem it encountered that caused it to abort. These values are defined in *application/config/constants.php*. While exit status codes are most useful in CLI settings, returning the proper code helps server software keep track of your scripts and the health of your application.

The following functions let you generate errors:

show_error()

show_error (*\$message*, *\$status_code*, *\$heading* = 'An Error Was Encountered')

- **\$message** (*mixed*) – Error message
- **\$status_code** (*int*) – HTTP Response status code
- **\$heading** (*string*) – Error page heading

void

This function will display the error message supplied to it using the following error template:

`application/views/errors/error_general.php`

The optional parameter `$status_code` determines what HTTP status code should be sent with the error. If `$status_code` is less than 100, the HTTP status code will be set to 500, and the exit status code will be set to `$status_code + EXIT__AUTO_MIN`. If that value is larger than `EXIT__AUTO_MAX`, or if `$status_code` is 100 or higher, the exit status code will be set to `EXIT_ERROR`. You can check in *application/config/constants.php* for more detail.

show_404()

show_404 (*\$page* = '', *\$log_error* = *TRUE*)

- **\$page** (*string*) – URI string
- **\$log_error** (*bool*) – Whether to log the error

void

This function will display the 404 error message supplied to it using the following error template:

`application/views/errors/error_404.php`

The function expects the string passed to it to be the file path to the page that isn't found. The exit status code will be set to `EXIT_UNKNOWN_FILE`. Note that CodeIgniter automatically shows 404 messages if controllers are not found.

CodeIgniter automatically logs any `show_404()` calls. Setting the optional second parameter to `FALSE` will skip logging.

log_message()

log_message (*\$level*, *\$message*, *\$php_error* = *FALSE*)

- **\$level** (*string*) – Log level: 'error', 'debug' or 'info'

- **\$message** (*string*) – Message to log
- **\$php_error** (*bool*) – Whether we’re logging a native PHP error message

void

This function lets you write messages to your log files. You must supply one of three “levels” in the first parameter, indicating what type of message it is (debug, error, info), with the message itself in the second parameter.

Example:

```
if ($some_var == '')
{
    log_message('error', 'Some variable did not contain a value.');
```

```
    }
else
{
    log_message('debug', 'Some variable was correctly set');
```

```
    }

log_message('info', 'The purpose of some variable is to provide some value.');
```

There are three message types:

1. Error Messages. These are actual errors, such as PHP errors or user errors.
2. Debug Messages. These are messages that assist in debugging. For example, if a class has been initialized, you could log this as debugging info.
3. Informational Messages. These are the lowest priority messages, simply giving information regarding some process. CodeIgniter doesn’t natively generate any info messages but you may want to in your application.

: In order for the log file to actually be written, the *logs* directory must be writable. In addition, you must set the “threshold” for logging in *application/config/config.php*. You might, for example, only want error messages to be logged, and not the other two types. If you set it to zero logging will be disabled.

6.1.18 Web Page Caching

CodeIgniter lets you cache your pages in order to achieve maximum performance.

Although CodeIgniter is quite fast, the amount of dynamic information you display in your pages will correlate directly to the server resources, memory, and processing cycles utilized, which affect your page load speeds. By caching your pages, since they are saved in their fully rendered state, you can achieve performance that nears that of static web pages.

How Does Caching Work?

Caching can be enabled on a per-page basis, and you can set the length of time that a page should remain cached before being refreshed. When a page is loaded for the first time, the cache file will be written to your application/cache folder. On subsequent page loads the cache file will be retrieved and sent to the requesting user’s browser. If it has expired, it will be deleted and refreshed before being sent to the browser.

Enabling Caching

To enable caching, put the following tag in any of your controller methods:

```
$this->output->cache($n);
```

Where `$n` is the number of **minutes** you wish the page to remain cached between refreshes.

The above tag can go anywhere within a method. It is not affected by the order that it appears, so place it wherever it seems most logical to you. Once the tag is in place, your pages will begin being cached.

: Because of the way CodeIgniter stores content for output, caching will only work if you are generating display for your controller with a *view*.

: Before the cache files can be written you must set the file permissions on your *application/cache/* directory such that it is writable.

Deleting Caches

If you no longer wish to cache a file you can remove the caching tag and it will no longer be refreshed when it expires.

: Removing the tag will not delete the cache immediately. It will have to expire normally.

If you need to manually delete the cache, you can use the `delete_cache()` method:

```
// Deletes cache for the currently requested URI
$this->output->delete_cache();
```

```
// Deletes cache for /foo/bar
$this->output->delete_cache('/foo/bar');
```

6.1.19 Profiling Your Application

The Profiler Class will display benchmark results, queries you have run, and `$_POST` data at the bottom of your pages. This information can be useful during development in order to help with debugging and optimization.

Initializing the Class

: This class does NOT need to be initialized. It is loaded automatically by the *Output Library* if profiling is enabled as shown below.

Enabling the Profiler

To enable the profiler place the following line anywhere within your *Controller* methods:

```
$this->output->enable_profiler(TRUE);
```

When enabled a report will be generated and inserted at the bottom of your pages.

To disable the profiler you will use:

```
$this->output->enable_profiler(FALSE);
```

Setting Benchmark Points

In order for the Profiler to compile and display your benchmark data you must name your mark points using specific syntax.

Please read the information on setting Benchmark points in the *Benchmark Library* page.

Enabling and Disabling Profiler Sections

Each section of Profiler data can be enabled or disabled by setting a corresponding config variable to TRUE or FALSE. This can be done one of two ways. First, you can set application wide defaults with the *application/config/profiler.php* config file.

Example:

```
$config['config']          = FALSE;
$config['queries']         = FALSE;
```

In your controllers, you can override the defaults and config file values by calling the `set_profiler_sections()` method of the *Output Library*:

```
$sections = array(
    'config' => TRUE,
    'queries' => TRUE
);

$this->output->set_profiler_sections($sections);
```

Available sections and the array key used to access them are described in the table below.

Key	Description	Default
benchmarks	Elapsed time of Benchmark points and total execution time	TRUE
config	CodeIgniter Config variables	TRUE
controller_info	The Controller class and method requested	TRUE
get	Any GET data passed in the request	TRUE
http_headers	The HTTP headers for the current request	TRUE
memory_usage	Amount of memory consumed by the current request, in bytes	TRUE
post	Any POST data passed in the request	TRUE
queries	Listing of all database queries executed, including execution time	TRUE
uri_string	The URI of the current request	TRUE
session_data	Data stored in the current session	TRUE
query_toggle_count	The number of queries after which the query block will default to hidden.	25

6.1.20 Running via the CLI

As well as calling an applications *Controllers* via the URL in a browser they can also be loaded via the command-line interface (CLI).

Page Contents

- Running via the CLI
 - What is the CLI?
 - Why run via the command-line?
 - Let's try it: Hello World!
 - That's it!

What is the CLI?

The command-line interface is a text-based method of interacting with computers. For more information, check the [Wikipedia article](#).

Why run via the command-line?

There are many reasons for running CodeIgniter from the command-line, but they are not always obvious.

- Run your cron-jobs without needing to use *wget* or *curl*
- Make your cron-jobs inaccessible from being loaded in the URL by checking the return value of `is_cli()`.
- Make interactive “tasks” that can do things like set permissions, prune cache folders, run backups, etc.
- Integrate with other applications in other languages. For example, a random C++ script could call one command and run code in your models!

Let’s try it: Hello World!

Let’s create a simple controller so you can see it in action. Using your text editor, create a file called `Tools.php`, and put the following code in it:

```
<?php
class Tools extends CI_Controller {

    public function message($to = 'World')
    {
        echo "Hello {$to}!".PHP_EOL;
    }
}
```

Then save the file to your *application/controllers/* folder.

Now normally you would visit the your site using a URL similar to this:

```
example.com/index.php/tools/message/to
```

Instead, we are going to open Terminal in Mac/Linux or go to Run > “cmd” in Windows and navigate to our CodeIgniter project.

```
$ cd /path/to/project;
$ php index.php tools message
```

If you did it right, you should see *Hello World!* printed.

```
$ php index.php tools message "John Smith"
```

Here we are passing it a argument in the same way that URL parameters work. “John Smith” is passed as a argument and output is:

```
Hello John Smith!
```

That’s it!

That, in a nutshell, is all there is to know about controllers on the command line. Remember that this is just a normal controller, so routing and `_remap()` works fine.

6.1.21 Managing your Applications

By default it is assumed that you only intend to use CodeIgniter to manage one application, which you will build in your *application/* directory. It is possible, however, to have multiple sets of applications that share a single CodeIgniter installation, or even to rename or relocate your application directory.

Renaming the Application Directory

If you would like to rename your application directory you may do so as long as you open your main index.php file and set its name using the `$application_folder` variable:

```
$application_folder = 'application';
```

Relocating your Application Directory

It is possible to move your application directory to a different location on your server than your web root. To do so open your main index.php and set a *full server path* in the `$application_folder` variable:

```
$application_folder = '/path/to/your/application';
```

Running Multiple Applications with one CodeIgniter Installation

If you would like to share a common CodeIgniter installation to manage several different applications simply put all of the directories located inside your application directory into their own sub-directory.

For example, let's say you want to create two applications, named “foo” and “bar”. You could structure your application directories like this:

```
applications/foo/
applications/foo/config/
applications/foo/controllers/
applications/foo/errors/
applications/foo/libraries/
applications/foo/models/
applications/foo/views/
applications/bar/
applications/bar/config/
applications/bar/controllers/
applications/bar/errors/
applications/bar/libraries/
applications/bar/models/
applications/bar/views/
```

To select a particular application for use requires that you open your main index.php file and set the `$application_folder` variable. For example, to select the “foo” application for use you would do this:

```
$application_folder = 'applications/foo';
```

: Each of your applications will need its own index.php file which calls the desired application. The index.php file can be named anything you want.

6.1.22 Handling Multiple Environments

Developers often desire different system behavior depending on whether an application is running in a development or production environment. For example, verbose error output is something that would be useful while developing an application, but it may also pose a security issue when “live”.

The ENVIRONMENT Constant

By default, CodeIgniter comes with the environment constant set to use the value provided in `$_SERVER['CI_ENV']`, otherwise defaults to ‘development’. At the top of `index.php`, you will see:

```
define('ENVIRONMENT', isset($_SERVER['CI_ENV']) ? $_SERVER['CI_ENV'] : 'development');
```

This server variable can be set in your `.htaccess` file, or Apache config using [SetEnv](#). Alternative methods are available for nginx and other servers, or you can remove this logic entirely and set the constant based on the `HTTP_HOST` or IP.

In addition to affecting some basic framework behavior (see the next section), you may use this constant in your own development to differentiate between which environment you are running in.

Effects On Default Framework Behavior

There are some places in the CodeIgniter system where the `ENVIRONMENT` constant is used. This section describes how default framework behavior is affected.

Error Reporting

Setting the `ENVIRONMENT` constant to a value of ‘development’ will cause all PHP errors to be rendered to the browser when they occur. Conversely, setting the constant to ‘production’ will disable all error output. Disabling error reporting in production is a *good security practice*.

Configuration Files

Optionally, you can have CodeIgniter load environment-specific configuration files. This may be useful for managing things like differing API keys across multiple environments. This is described in more detail in the environment section of the [Config Class](#) documentation.

6.1.23 Alternate PHP Syntax for View Files

If you do not utilize CodeIgniter’s *template engine*, you’ll be using pure PHP in your View files. To minimize the PHP code in these files, and to make it easier to identify the code blocks it is recommended that you use PHP’s alternative syntax for control structures and short tag echo statements. If you are not familiar with this syntax, it allows you to eliminate the braces from your code, and eliminate “echo” statements.

Automatic Short Tag Support

: If you find that the syntax described in this page does not work on your server it might be that “short tags” are disabled in your PHP ini file. CodeIgniter will optionally rewrite short tags on-the-fly, allowing you to use that syntax even if your server doesn’t support it. This feature can be enabled in your `config/config.php` file.

Please note that if you do use this feature, if PHP errors are encountered in your **view files**, the error message and line number will not be accurately shown. Instead, all errors will be shown as `eval()` errors.

Alternative Echos

Normally to echo, or print out a variable you would do this:

```
<?php echo $variable; ?>
```

With the alternative syntax you can instead do it this way:

```
<?=$variable?>
```

Alternative Control Structures

Controls structures, like if, for, foreach, and while can be written in a simplified format as well. Here is an example using foreach:

```
<ul>

<?php foreach ($todo as $item): ?>

    <li><?=$item?></li>

<?php endforeach; ?>

</ul>
```

Notice that there are no braces. Instead, the end brace is replaced with `endforeach`. Each of the control structures listed above has a similar closing syntax: `endif`, `endfor`, `endforeach`, and `endwhile`

Also notice that instead of using a semicolon after each structure (except the last one), there is a colon. This is important!

Here is another example, using `if/elseif/else`. Notice the colons:

```
<?php if ($username === 'sally'): ?>

    <h3>Hi Sally</h3>

<?php elseif ($username === 'joe'): ?>

    <h3>Hi Joe</h3>

<?php else: ?>

    <h3>Hi unknown user</h3>

<?php endif; ?>
```

6.1.24 Security

This page describes some “best practices” regarding web security, and details CodeIgniter’s internal security features.

URI Security

CodeIgniter is fairly restrictive regarding which characters it allows in your URI strings in order to help minimize the possibility that malicious data can be passed to your application. URIs may only contain the following:

- Alpha-numeric text (latin characters only)
- Tilde: ~
- Percent sign: %
- Period: .
- Colon: :
- Underscore: _
- Dash: -
- Space

Register_globals

During system initialization all global variables are unset, except those found in the `$_GET`, `$_POST`, and `$_COOKIE` arrays. The unsetting routine is effectively the same as `register_globals = off`.

display_errors

In production environments, it is typically desirable to “disable” PHP’s error reporting by setting the internal `display_errors` flag to a value of 0. This disables native PHP errors from being rendered as output, which may potentially contain sensitive information.

Setting CodeIgniter’s **ENVIRONMENT** constant in `index.php` to a value of ‘**production**’ will turn off these errors. In development mode, it is recommended that a value of ‘development’ is used. More information about differentiating between environments can be found on the *Handling Environments* page.

magic_quotes_runtime

The `magic_quotes_runtime` directive is turned off during system initialization so that you don’t have to remove slashes when retrieving data from your database.

Best Practices

Before accepting any data into your application, whether it be POST data from a form submission, COOKIE data, URI data, XML-RPC data, or even data from the SERVER array, you are encouraged to practice this three step approach:

1. Filter the data as if it were tainted.
2. Validate the data to ensure it conforms to the correct type, length, size, etc. (sometimes this step can replace step one)
3. Escape the data before submitting it into your database.

CodeIgniter provides the following functions to assist in this process:

XSS Filtering

CodeIgniter comes with a Cross Site Scripting filter. This filter looks for commonly used techniques to embed malicious JavaScript into your data, or other types of code that attempt to hijack cookies or do other malicious things. The XSS Filter is described *here*.

Validate the data

CodeIgniter has a *Form Validation Library* that assists you in validating, filtering, and prepping your data.

Escape all data before database insertion

Never insert information into your database without escaping it. Please see the section that discusses *database queries* for more information.

Hide your files

Another good security practice is to only leave your *index.php* and “assets” (e.g. .js, css and image files) under your server’s *webroot* directory (most commonly named “htdocs/”). These are the only files that you would need to be accessible from the web.

Allowing your visitors to see anything else would potentially allow them to access sensitive data, execute scripts, etc.

If you’re not allowed to do that, you can try using a .htaccess file to restrict access to those resources.

CodeIgniter will have an index.html file in all of its directories in an attempt to hide some of this data, but have it in mind that this is not enough to prevent a serious attacker.

6.1.25 PHP Style Guide

The following page describes the coding styles adhered to when contributing to the development of CodeIgniter. There is no requirement to use these styles in your own CodeIgniter application, though they are recommended.

Table of Contents

- PHP Style Guide
 - File Format
 - * TextMate
 - * BBEdit
 - PHP Closing Tag
 - File Naming
 - Class and Method Naming
 - Variable Names
 - Commenting
 - Constants
 - TRUE, FALSE, and NULL
 - Logical Operators
 - Comparing Return Values and Typecasting
 - Debugging Code
 - Whitespace in Files
 - Compatibility
 - One File per Class
 - Whitespace
 - Line Breaks
 - Code Indenting
 - Bracket and Parenthetic Spacing
 - Localized Text
 - Private Methods and Variables
 - PHP Errors
 - Short Open Tags
 - One Statement Per Line
 - Strings
 - SQL Queries
 - Default Function Arguments

File Format

Files should be saved with Unicode (UTF-8) encoding. The BOM should *not* be used. Unlike UTF-16 and UTF-32, there's no byte order to indicate in a UTF-8 encoded file, and the BOM can have a negative side effect in PHP of sending output, preventing the application from being able to set its own headers. Unix line endings should be used (LF).

Here is how to apply these settings in some of the more common text editors. Instructions for your text editor may vary; check your text editor's documentation.

TextMate

1. Open the Application Preferences
2. Click Advanced, and then the "Saving" tab
3. In "File Encoding", select "UTF-8 (recommended)"
4. In "Line Endings", select "LF (recommended)"
5. *Optional:* Check "Use for existing files as well" if you wish to modify the line endings of files you open to your new preference.

BBEdit

1. Open the Application Preferences
2. Select “Text Encodings” on the left.
3. In “Default text encoding for new documents”, select “Unicode (UTF-8, no BOM)”
4. *Optional:* In “If file’s encoding can’t be guessed, use”, select “Unicode (UTF-8, no BOM)”
5. Select “Text Files” on the left.
6. In “Default line breaks”, select “Mac OS X and Unix (LF)”

PHP Closing Tag

The PHP closing tag on a PHP document `?>` is optional to the PHP parser. However, if used, any whitespace following the closing tag, whether introduced by the developer, user, or an FTP application, can cause unwanted output, PHP errors, or if the latter are suppressed, blank pages. For this reason, all PHP files should **OMIT** the closing PHP tag, and instead use a comment block to mark the end of file and its location relative to the application root. This allows you to still identify a file as being complete and not truncated.

INCORRECT:

```
<?php

echo "Here's my code!";

?>
```

CORRECT:

```
<?php

echo "Here's my code!";

/* End of file Myfile.php */
/* Location: ./system/modules/mymodule/myfile.php */
```

: There should be no empty line or newline character(s) following the closing comments. If you happen to see one when submitting a pull request, please check your IDE settings and fix it.

File Naming

Class files must be named in a Ucfirst-like manner, while any other file name (configurations, views, generic scripts, etc.) should be in all lowercase.

INCORRECT:

```
somelibrary.php
someLibrary.php
SOMELIBRARY.php
Some_Library.php

Application_config.php
Application_Config.php
applicationConfig.php
```

CORRECT:

```
Somelibrary.php
Some_library.php

applicationconfig.php
application_config.php
```

Furthermore, class file names should match the name of the class itself. For example, if you have a class named *Myclass*, then its filename must be **Myclass.php**.

Class and Method Naming

Class names should always start with an uppercase letter. Multiple words should be separated with an underscore, and not CamelCased.

INCORRECT:

```
class superclass
class SuperClass
```

CORRECT:

```
class Super_class

class Super_class {

    public function __construct()
    {

    }

}
```

Class methods should be entirely lowercased and named to clearly indicate their function, preferably including a verb. Try to avoid overly long and verbose names. Multiple words should be separated with an underscore.

INCORRECT:

```
function fileproperties()           // not descriptive and needs underscore separator
function fileProperties()           // not descriptive and uses CamelCase
function getfileproperties()        // Better! But still missing underscore separator
function getFileProperties()        // uses CamelCase
function get_the_file_properties_from_the_file() // wordy
```

CORRECT:

```
function get_file_properties() // descriptive, underscore separator, and all lowercase letters
```

Variable Names

The guidelines for variable naming are very similar to those used for class methods. Variables should contain only lowercase letters, use underscore separators, and be reasonably named to indicate their purpose and contents. Very short, non-word variables should only be used as iterators in `for()` loops.

INCORRECT:

```

$j = 'foo';           // single letter variables should only be used in for() loops
$str                 // contains uppercase letters
$bufferedText       // uses CamelCasing, and could be shortened without losing semantic meaning
$groupid             // multiple words, needs underscore separator
$name_of_last_city_used // too long

```

CORRECT:

```

for ($j = 0; $j < 10; $j++)
$str
$buffer
$group_id
$last_city

```

Commenting

In general, code should be commented prolifically. It not only helps describe the flow and intent of the code for less experienced programmers, but can prove invaluable when returning to your own code months down the line. There is not a required format for comments, but the following are recommended.

DocBlock style comments preceding class, method, and property declarations so they can be picked up by IDEs:

```

/**
 * Super Class
 *
 * @package      Package Name
 * @subpackage   Subpackage
 * @category     Category
 * @author       Author Name
 * @link         http://example.com
 */
class Super_class {

/**
 * Encodes string for use in XML
 *
 * @param        string  $str    Input string
 * @return       string
 */
function xml_encode($str)

/**
 * Data for class manipulation
 *
 * @var array
 */
public $data = array();

```

Use single line comments within code, leaving a blank line between large comment blocks and code.

```

// break up the string by newlines
$parts = explode("\n", $str);

// A longer comment that needs to give greater detail on what is
// occurring and why can use multiple single-line comments. Try to
// keep the width reasonable, around 70 characters is the easiest to
// read. Don't hesitate to link to permanent external resources
// that may provide greater detail:

```

```
//  
// http://example.com/information_about_something/in_particular/  
  
$parts = $this->foo($parts);
```

Constants

Constants follow the same guidelines as do variables, except constants should always be fully uppercase. *Always use CodeIgniter constants when appropriate, i.e. SLASH, LD, RD, PATH_CACHE, etc.*

INCORRECT:

```
myConstant      // missing underscore separator and not fully uppercase  
N               // no single-letter constants  
S_C_VER         // not descriptive  
$str = str_replace('{foo}', 'bar', $str);           // should use LD and RD constants
```

CORRECT:

```
MY_CONSTANT  
NEWLINE  
SUPER_CLASS_VERSION  
$str = str_replace(LD.'foo'.RD, 'bar', $str);
```

TRUE, FALSE, and NULL

TRUE, FALSE, and NULL keywords should always be fully uppercase.

INCORRECT:

```
if ($foo == true)  
$bar = false;  
function foo($bar = null)
```

CORRECT:

```
if ($foo == TRUE)  
$bar = FALSE;  
function foo($bar = NULL)
```

Logical Operators

Use of the || “or” comparison operator is discouraged, as its clarity on some output devices is low (looking like the number 11, for instance). && is preferred over AND but either are acceptable, and a space should always precede and follow !.

INCORRECT:

```
if ($foo || $bar)  
if ($foo AND $bar) // okay but not recommended for common syntax highlighting applications  
if (!$foo)  
if (! is_array($foo))
```

CORRECT:

```

if ($foo OR $bar)
if ($foo && $bar) // recommended
if ( ! $foo)
if ( ! is_array($foo))

```

Comparing Return Values and Typecasting

Some PHP functions return FALSE on failure, but may also have a valid return value of "" or 0, which would evaluate to FALSE in loose comparisons. Be explicit by comparing the variable type when using these return values in conditionals to ensure the return value is indeed what you expect, and not a value that has an equivalent loose-type evaluation.

Use the same stringency in returning and checking your own variables. Use === and !== as necessary.

INCORRECT:

```

// If 'foo' is at the beginning of the string, strpos will return a 0,
// resulting in this conditional evaluating as TRUE
if (strpos($str, 'foo') == FALSE)

```

CORRECT:

```

if (strpos($str, 'foo') === FALSE)

```

INCORRECT:

```

function build_string($str = "")
{
    if ($str == "") // uh-oh!  What if FALSE or the integer 0 is passed as an argument?
    {

    }
}

```

CORRECT:

```

function build_string($str = "")
{
    if ($str === "")
    {

    }
}

```

See also information regarding [typecasting](#), which can be quite useful. Typecasting has a slightly different effect which may be desirable. When casting a variable as a string, for instance, NULL and boolean FALSE variables become empty strings, 0 (and other numbers) become strings of digits, and boolean TRUE becomes "1":

```

$str = (string) $str; // cast $str as a string

```

Debugging Code

Do not leave debugging code in your submissions, even when commented out. Things such as `var_dump()`, `print_r()`, `die()/exit()` should not be included in your code unless it serves a specific purpose other than debugging.

Whitespace in Files

No whitespace can precede the opening PHP tag or follow the closing PHP tag. Output is buffered, so whitespace in your files can cause output to begin before CodeIgniter outputs its content, leading to errors and an inability for CodeIgniter to send proper headers.

Compatibility

CodeIgniter requires a minimum PHP version of 5.2.4. Your code must either be compatible with this minimum requirement, provide a suitable fallback, or be an optional feature that dies quietly without affecting a user's application.

Additionally, do not use PHP functions that require non-default libraries to be installed unless your code contains an alternative method when the function is not available.

One File per Class

Use separate files for each class, unless the classes are *closely related*. An example of a CodeIgniter file that contains multiple classes is the Xmlrpc library file.

Whitespace

Use tabs for whitespace in your code, not spaces. This may seem like a small thing, but using tabs instead of whitespace allows the developer looking at your code to have indentation at levels that they prefer and customize in whatever application they use. And as a side benefit, it results in (slightly) more compact files, storing one tab character versus, say, four space characters.

Line Breaks

Files must be saved with Unix line breaks. This is more of an issue for developers who work in Windows, but in any case ensure that your text editor is setup to save files with Unix line breaks.

Code Indenting

Use Allman style indenting. With the exception of Class declarations, braces are always placed on a line by themselves, and indented at the same level as the control statement that “owns” them.

INCORRECT:

```
function foo($bar) {
    // ...
}

foreach ($arr as $key => $val) {
    // ...
}

if ($foo == $bar) {
    // ...
} else {
    // ...
}

for ($i = 0; $i < 10; $i++)
```

```
        {
            for ($j = 0; $j < 10; $j++)
            {
                // ...
            }
        }

try {
    // ...
}
catch() {
    // ...
}
```

CORRECT:

```
function foo($bar)
{
    // ...
}

foreach ($arr as $key => $val)
{
    // ...
}

if ($foo == $bar)
{
    // ...
}
else
{
    // ...
}

for ($i = 0; $i < 10; $i++)
{
    for ($j = 0; $j < 10; $j++)
    {
        // ...
    }
}

try
{
    // ...
}
catch()
{
    // ...
}
```

Bracket and Parenthetic Spacing

In general, parenthesis and brackets should not use any additional spaces. The exception is that a space should always follow PHP control structures that accept arguments with parenthesis (declare, do-while, elseif, for, foreach, if, switch, while), to help distinguish them from functions and increase readability.

INCORRECT:

```
$arr[ $foo ] = 'foo';
```

CORRECT:

```
$arr[$foo] = 'foo'; // no spaces around array keys
```

INCORRECT:

```
function foo ( $bar )  
{  
  
}
```

CORRECT:

```
function foo($bar) // no spaces around parenthesis in function declarations  
{  
  
}
```

INCORRECT:

```
foreach( $query->result() as $row )
```

CORRECT:

```
foreach ($query->result() as $row) // single space following PHP control structures, but not in inter
```

Localized Text

CodeIgniter libraries should take advantage of corresponding language files whenever possible.

INCORRECT:

```
return "Invalid Selection";
```

CORRECT:

```
return $this->lang->line('invalid_selection');
```

Private Methods and Variables

Methods and variables that are only accessed internally, such as utility and helper functions that your public methods use for code abstraction, should be prefixed with an underscore.

```
public function convert_text()  
private function _convert_text()
```

PHP Errors

Code must run error free and not rely on warnings and notices to be hidden to meet this requirement. For instance, never access a variable that you did not set yourself (such as `$_POST` array keys) without first checking to see that it `isset()`.

Make sure that your dev environment has error reporting enabled for ALL users, and that `display_errors` is enabled in the PHP environment. You can check this setting with:

```
if (ini_get('display_errors') == 1)
{
    exit "Enabled";
}
```

On some servers where *display_errors* is disabled, and you do not have the ability to change this in the `php.ini`, you can often enable it with:

```
ini_set('display_errors', 1);
```

: Setting the `display_errors` setting with `ini_set()` at runtime is not identical to having it enabled in the PHP environment. Namely, it will not have any effect if the script has fatal errors.

Short Open Tags

Always use full PHP opening tags, in case a server does not have *short_open_tag* enabled.

INCORRECT:

```
<? echo $foo; ?>

<?=$foo?>
```

CORRECT:

```
<?php echo $foo; ?>
```

: PHP 5.4 will always have the `<?=>` tag available.

One Statement Per Line

Never combine statements on one line.

INCORRECT:

```
$foo = 'this'; $bar = 'that'; $bat = str_replace($foo, $bar, $bag);
```

CORRECT:

```
$foo = 'this';
$bar = 'that';
$bat = str_replace($foo, $bar, $bag);
```

Strings

Always use single quoted strings unless you need variables parsed, and in cases where you do need variables parsed, use braces to prevent greedy token parsing. You may also use double-quoted strings if the string contains single quotes, so you do not have to use escape characters.

INCORRECT:

```
"My String"                // no variable parsing, so no use for double quotes
"My string $foo"            // needs braces
'SELECT foo FROM bar WHERE baz = \'bag\'' // ugly
```

CORRECT:

```
'My String'
"My string {$foo}"
"SELECT foo FROM bar WHERE baz = 'bag'"
```

SQL Queries

SQL keywords are always capitalized: SELECT, INSERT, UPDATE, WHERE, AS, JOIN, ON, IN, etc.

Break up long queries into multiple lines for legibility, preferably breaking for each clause.

INCORRECT:

```
// keywords are lowercase and query is too long for
// a single line (... indicates continuation of line)
$query = $this->db->query("select foo, bar, baz, foofoo, foobar as raboof, foobaz from exp_pre_email
...where foo != 'oof' and baz != 'zab' order by foobaz limit 5, 100");
```

CORRECT:

```
$query = $this->db->query("SELECT foo, bar, baz, foofoo, foobar AS raboof, foobaz
                        FROM exp_pre_email_addresses
                        WHERE foo != 'oof'
                        AND baz != 'zab'
                        ORDER BY foobaz
                        LIMIT 5, 100");
```

Default Function Arguments

Whenever appropriate, provide function argument defaults, which helps prevent PHP errors with mistaken calls and provides common fallback values which can save a few lines of code. Example:

```
function foo($bar = '', $baz = FALSE)
```

7.1 Libraries

7.1.1 Benchmarking Class

CodeIgniter has a Benchmarking class that is always active, enabling the time difference between any two marked points to be calculated.

: This class is initialized automatically by the system so there is no need to do it manually.

In addition, the benchmark is always started the moment the framework is invoked, and ended by the output class right before sending the final view to the browser, enabling a very accurate timing of the entire system execution to be shown.

Table of Contents

- Benchmarking Class
 - Using the Benchmark Class
 - Profiling Your Benchmark Points
 - Displaying Total Execution Time
 - Displaying Memory Consumption

Using the Benchmark Class

The Benchmark class can be used within your *controllers*, *views*, or your *models*. The process for usage is this:

1. Mark a start point
2. Mark an end point
3. Run the “elapsed time” function to view the results

Here’s an example using real code:

```
$this->benchmark->mark('code_start');  
  
// Some code happens here  
  
$this->benchmark->mark('code_end');
```

```
echo $this->benchmark->elapsed_time('code_start', 'code_end');
```

: The words “code_start” and “code_end” are arbitrary. They are simply words used to set two markers. You can use any words you want, and you can set multiple sets of markers. Consider this example:

```
$this->benchmark->mark('dog');

// Some code happens here

$this->benchmark->mark('cat');

// More code happens here

$this->benchmark->mark('bird');

echo $this->benchmark->elapsed_time('dog', 'cat');
echo $this->benchmark->elapsed_time('cat', 'bird');
echo $this->benchmark->elapsed_time('dog', 'bird');
```

Profiling Your Benchmark Points

If you want your benchmark data to be available to the *Profiler* all of your marked points must be set up in pairs, and each mark point name must end with `_start` and `_end`. Each pair of points must otherwise be named identically. Example:

```
$this->benchmark->mark('my_mark_start');

// Some code happens here...

$this->benchmark->mark('my_mark_end');

$this->benchmark->mark('another_mark_start');

// Some more code happens here...

$this->benchmark->mark('another_mark_end');
```

Please read the *Profiler* page for more information.

Displaying Total Execution Time

If you would like to display the total elapsed time from the moment CodeIgniter starts to the moment the final output is sent to the browser, simply place this in one of your view templates:

```
<?php echo $this->benchmark->elapsed_time();?>
```

You’ll notice that it’s the same function used in the examples above to calculate the time between two point, except you are **not** using any parameters. When the parameters are absent, CodeIgniter does not stop the benchmark until right before the final output is sent to the browser. It doesn’t matter where you use the function call, the timer will continue to run until the very end.

An alternate way to show your elapsed time in your view files is to use this pseudo-variable, if you prefer not to use the pure PHP:

```
{elapsed_time}
```

: If you want to benchmark anything within your controller functions you must set your own start/end points.

Displaying Memory Consumption

If your PHP installation is configured with `--enable-memory-limit`, you can display the amount of memory consumed by the entire system using the following code in one of your view file:

```
<?php echo $this->benchmark->memory_usage();?>
```

: This function can only be used in your view files. The consumption will reflect the total memory used by the entire app.

An alternate way to show your memory usage in your view files is to use this pseudo-variable, if you prefer not to use the pure PHP:

```
{memory_usage}
```

7.1.2 Caching Driver

CodeIgniter features wrappers around some of the most popular forms of fast and dynamic caching. All but file-based caching require specific server requirements, and a Fatal Exception will be thrown if server requirements are not met.

Table of Contents

- Caching Driver
 - Example Usage
 - Function Reference
 - * `is_supported()`
 - * `get()`
 - * `save()`
 - * `delete()`
 - * `clean()`
 - * `cache_info()`
 - * `get_metadata()`
 - Drivers
 - * Alternative PHP Cache (APC) Caching
 - * File-based Caching
 - * Memcached Caching
 - * WinCache Caching
 - * Redis Caching
 - * Dummy Cache

Example Usage

The following example will load the cache driver, specify APC as the driver to use, and fall back to file-based caching if APC is not available in the hosting environment.

```
$this->load->driver('cache', array('adapter' => 'apc', 'backup' => 'file'));

if ( ! $foo = $this->cache->get('foo'))
{
    echo 'Saving to the cache!<br />';
    $foo = 'foobarbaz!';

    // Save into the cache for 5 minutes
    $this->cache->save('foo', $foo, 300);
}

echo $foo;
```

You can also prefix cache item names via the **key_prefix** setting, which is useful to avoid collisions when you're running multiple applications on the same environment.

```
$this->load->driver('cache',
    array('adapter' => 'apc', 'backup' => 'file', 'key_prefix' => 'my_')
);

$this->cache->get('foo'); // Will get the cache entry named 'my_foo'
```

Function Reference

class **CI_Cache**

is_supported()

CI_Cache::is_supported(\$driver)

This function is automatically called when accessing drivers via `$this->cache->get()`. However, if the individual drivers are used, make sure to call this function to ensure the driver is supported in the hosting environment.

- **\$driver** (*string*) – the name of the caching driver

TRUE if supported, FALSE if not

Boolean

```
if ($this->cache->apc->is_supported())
{
    if ($data = $this->cache->apc->get('my_cache'))
    {
        // do things.
    }
}
```

get()

CI_Cache::get(\$id)

This function will attempt to fetch an item from the cache store. If the item does not exist, the function will return FALSE.

- **\$id** (*string*) – name of cached item

The item if it exists, FALSE if it does not

Mixed

```
$foo = $this->cache->get('my_cached_item');
```

save()

```
CI_Cache::save($id, $data[, $ttl])
```

This function will save an item to the cache store. If saving fails, the function will return FALSE.

- **\$id** (*string*) – name of the cached item
- **\$data** (*mixed*) – the data to save
- **\$ttl** (*int*) – Time To Live, in seconds (default 60)

TRUE on success, FALSE on failure

Boolean

```
$this->cache->save('cache_item_id', 'data_to_cache');
```

delete()

```
CI_Cache::delete($id)
```

This function will delete a specific item from the cache store. If item deletion fails, the function will return FALSE.

- **\$id** (*string*) – name of cached item

TRUE if deleted, FALSE if the deletion fails

Boolean

```
$this->cache->delete('cache_item_id');
```

clean()

```
CI_Cache::clean()
```

This function will 'clean' the entire cache. If the deletion of the cache files fails, the function will return FALSE.

TRUE if deleted, FALSE if the deletion fails

Boolean

```
$this->cache->clean();
```

cache_info()

CI_Cache::cache_info()

This function will return information on the entire cache.

information on the entire cache

Mixed

```
var_dump($this->cache->cache_info());
```

: The information returned and the structure of the data is dependent on which adapter is being used.

get_metadata()

CI_Cache::get_metadata(\$id)

This function will return detailed information on a specific item in the cache.

- **\$id** (*string*) – name of cached item

metadadta for the cached item

Mixed

```
var_dump($this->cache->get_metadata('my_cached_item'));
```

: The information returned and the structure of the data is dependent on which adapter is being used.

Drivers**Alternative PHP Cache (APC) Caching**

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->apc->save('foo', 'bar', 10);
```

For more information on APC, please see <http://php.net/apc>.

File-based Caching

Unlike caching from the Output Class, the driver file-based caching allows for pieces of view files to be cached. Use this with care, and make sure to benchmark your application, as a point can come where disk I/O will negate positive gains by caching.

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->file->save('foo', 'bar', 10);
```

Memcached Caching

Multiple Memcached servers can be specified in the memcached.php configuration file, located in the `_application/config/*` directory.

All of the methods listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');
$this->cache->memcached->save('foo', 'bar', 10);
```

For more information on Memcached, please see <http://php.net/memcached>.

WinCache Caching

Under Windows, you can also utilize the WinCache driver.

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');
$this->cache->wincache->save('foo', 'bar', 10);
```

For more information on WinCache, please see <http://php.net/wincache>.

Redis Caching

Redis is an in-memory key-value store which can operate in LRU cache mode. To use it, you need Redis server and phpredis PHP extension <https://github.com/nicolasff/phpredis>.

Config options to connect to redis server must be stored in the `application/config/redis.php` file. Available options are:

```
$config['socket_type'] = 'tcp'; // 'tcp' or 'unix'
$config['socket'] = '/var/run/redis.sock'; // in case of 'unix' socket type
$config['host'] = '127.0.0.1';
$config['password'] = NULL;
$config['port'] = 6379;
$config['timeout'] = 0;
```

All of the methods listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');
$this->cache->redis->save('foo', 'bar', 10);
```

For more information on Redis, please see <http://redis.io>.

Dummy Cache

This is a caching backend that will always 'miss.' It stores no data, but lets you keep your caching code in place in environments that don't support your chosen cache.

7.1.3 Calendaring Class

The Calendar class enables you to dynamically create calendars. Your calendars can be formatted through the use of a calendar template, allowing 100% control over every aspect of its design. In addition, you can pass data to your calendar cells.

Initializing the Class

Like most other classes in CodeIgniter, the Calendar class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('calendar');
```

Once loaded, the Calendar object will be available using:

```
$this->calendar
```

Displaying a Calendar

Here is a very simple example showing how you can display a calendar:

```
$this->load->library('calendar');  
echo $this->calendar->generate();
```

The above code will generate a calendar for the current month/year based on your server time. To show a calendar for a specific month and year you will pass this information to the calendar generating function:

```
$this->load->library('calendar');  
echo $this->calendar->generate(2006, 6);
```

The above code will generate a calendar showing the month of June in 2006. The first parameter specifies the year, the second parameter specifies the month.

Passing Data to your Calendar Cells

To add data to your calendar cells involves creating an associative array in which the keys correspond to the days you wish to populate and the array value contains the data. The array is passed to the third parameter of the calendar generating function. Consider this example:

```
$this->load->library('calendar');  
  
$data = array(  
    3 => 'http://example.com/news/article/2006/03/',  
    7 => 'http://example.com/news/article/2006/07/',  
    13 => 'http://example.com/news/article/2006/13/',  
    26 => 'http://example.com/news/article/2006/26/'  
);  
  
echo $this->calendar->generate(2006, 6, $data);
```

Using the above example, day numbers 3, 7, 13, and 26 will become links pointing to the URLs you've provided.

: By default it is assumed that your array will contain links. In the section that explains the calendar template below you'll see how you can customize how data passed to your cells is handled so you can pass different types of information.

Setting Display Preferences

There are seven preferences you can set to control various aspects of the calendar. Preferences are set by passing an array of preferences in the second parameter of the loading function. Here is an example:

```
$prefs = array (
    'start_day'      => 'saturday',
    'month_type'     => 'long',
    'day_type'       => 'short'
);
```

```
$this->load->library('calendar', $prefs);
```

```
echo $this->calendar->generate();
```

The above code would start the calendar on saturday, use the “long” month heading, and the “short” day names. More information regarding preferences below.

Preference	Default	Options	Description
template	None	None	A string containing your calendar template. See the template section below.
local_time	time()	None	A Unix timestamp corresponding to the current time.
start_day	sunday	Any week day (sunday, monday, tuesday, etc.)	Sets the day of the week the calendar should start on.
month_type	long	long, short	Determines what version of the month name to use in the header. long = January, short = Jan.
day_type	abr	long, short, abr	Determines what version of the weekday names to use in the column headers. long = Sunday, short = Sun, abr = Su.
show_next_prev	FALSE	SET TRUE/FALSE (boolean)	Determines whether to display links allowing you to toggle to next/previous months. See information on this feature below.
next_prev_url	None	A URL	Sets the basepath used in the next/previous calendar links.

Showing Next/Previous Month Links

To allow your calendar to dynamically increment/decrement via the next/previous links requires that you set up your calendar code similar to this example:

```
$prefs = array (
    'show_next_prev' => TRUE,
    'next_prev_url'  => 'http://example.com/index.php/calendar/show/'
);
```

```
$this->load->library('calendar', $prefs);
```

```
echo $this->calendar->generate($this->uri->segment(3), $this->uri->segment(4));
```

You’ll notice a few things about the above example:

- You must set the “show_next_prev” to TRUE.
- You must supply the URL to the controller containing your calendar in the “next_prev_url” preference.
- You must supply the “year” and “month” to the calendar generating function via the URI segments where they appear (Note: The calendar class automatically adds the year/month to the base URL you provide.).

Creating a Calendar Template

By creating a calendar template you have 100% control over the design of your calendar. Each component of your calendar will be placed within a pair of pseudo-variables as shown here:

```
$prefs['template'] = '

{table_open}<table border="0" cellpadding="0" cellspacing="0">{/table_open}

{heading_row_start}<tr>{/heading_row_start}

{heading_previous_cell}<th><a href="{previous_url}">&lt;&lt;</a></th>{/heading_previous_cell}
{heading_title_cell}<th colspan="{colspan}">{heading}</th>{/heading_title_cell}
{heading_next_cell}<th><a href="{next_url}">&gt;&gt;</a></th>{/heading_next_cell}

{heading_row_end}</tr>{/heading_row_end}

{week_row_start}<tr>{/week_row_start}
{week_day_cell}<td>{week_day}</td>{/week_day_cell}
{week_row_end}</tr>{/week_row_end}

{cal_row_start}<tr>{/cal_row_start}
{cal_cell_start}<td>{/cal_cell_start}

{cal_cell_content}<a href="{content}">{day}</a>{/cal_cell_content}
{cal_cell_content_today}<div class="highlight"><a href="{content}">{day}</a></div>{/cal_cell_content}

{cal_cell_no_content}{day}{/cal_cell_no_content}
{cal_cell_no_content_today}<div class="highlight">{day}</div>{/cal_cell_no_content_today}

{cal_cell_blank}&nbsp;{/cal_cell_blank}

{cal_cell_end}</td>{/cal_cell_end}
{cal_row_end}</tr>{/cal_row_end}

{table_close}</table>{/table_close}
';

$this->load->library('calendar', $prefs);

echo $this->calendar->generate();
```

7.1.4 Shopping Cart Class

The Cart Class permits items to be added to a session that stays active while a user is browsing your site. These items can be retrieved and displayed in a standard “shopping cart” format, allowing the user to update the quantity or remove items from the cart.

Please note that the Cart Class ONLY provides the core “cart” functionality. It does not provide shipping, credit card authorization, or other processing components.

 - * `$this->cart->update();`
 - * `$this->cart->remove(rowid);`
 - * `$this->cart->total();`
 - * `$this->cart->total_items();`
 - * `$this->cart->contents(boolean);`
 - * `$this->cart->get_item($row_id);`
 - * `$this->cart->has_options($row_id);`
 - * `$this->cart->product_options($row_id);`
 - * `$this->cart->destroy();`

Initializing the Shopping Cart Class

: The Cart class utilizes CodeIgniter's *Session Class* to save the cart information to a database, so before using the Cart class you must set up a database table as indicated in the *Session Documentation*, and set the session preferences in your application/config/config.php file to utilize a database.

To initialize the Shopping Cart Class in your controller constructor, use the `$this->load->library` function:

```
$this->load->library('cart');
```

Once loaded, the Cart object will be available using:

```
$this->cart
```

: The Cart Class will load and initialize the Session Class automatically, so unless you are using sessions elsewhere in your application, you do not need to load the Session class.

Adding an Item to The Cart

To add an item to the shopping cart, simply pass an array with the product information to the `$this->cart->insert()` function, as shown below:

```
$data = array(
    'id'      => 'sku_123ABC',
    'qty'     => 1,
    'price'   => 39.95,
    'name'    => 'T-Shirt',
    'options' => array('Size' => 'L', 'Color' => 'Red')
);

$this->cart->insert($data);
```

: The first four array indexes above (id, qty, price, and name) are **required**. If you omit any of them the data will not be saved to the cart. The fifth index (options) is optional. It is intended to be used in cases where your product has options associated with it. Use an array for options, as shown above.

The five reserved indexes are:

- **id** - Each product in your store must have a unique identifier. Typically this will be an “sku” or other such identifier.
- **qty** - The quantity being purchased.
- **price** - The price of the item.
- **name** - The name of the item.
- **options** - Any additional attributes that are needed to identify the product. These must be passed via an array.

In addition to the five indexes above, there are two reserved words: rowid and subtotal. These are used internally by the Cart class, so please do NOT use those words as index names when inserting data into the cart.

Your array may contain additional data. Anything you include in your array will be stored in the session. However, it is best to standardize your data among all your products in order to make displaying the information in a table easier.

The insert() method will return the \$rowid if you successfully insert a single item.

Adding Multiple Items to The Cart

By using a multi-dimensional array, as shown below, it is possible to add multiple products to the cart in one action. This is useful in cases where you wish to allow people to select from among several items on the same page.

```
$data = array(
    array(
        'id'      => 'sku_123ABC',
        'qty'     => 1,
        'price'   => 39.95,
        'name'    => 'T-Shirt',
        'options' => array('Size' => 'L', 'Color' => 'Red')
    ),
    array(
        'id'      => 'sku_567ZYX',
        'qty'     => 1,
        'price'   => 9.95,
        'name'    => 'Coffee Mug'
    ),
    array(
        'id'      => 'sku_965QRS',
        'qty'     => 1,
        'price'   => 29.95,
        'name'    => 'Shot Glass'
    )
);

$this->cart->insert($data);
```

Displaying the Cart

To display the cart you will create a *view file* with code similar to the one shown below.

Please note that this example uses the *form helper*.

```
<?php echo form_open('path/to/controller/update/function'); ?>

<table cellpadding="6" cellspacing="1" style="width:100%" border="0">

<tr>
    <th>QTY</th>
    <th>Item Description</th>
    <th style="text-align:right">Item Price</th>
    <th style="text-align:right">Sub-Total</th>
</tr>

<?php $i = 1; ?>

<?php foreach ($this->cart->contents() as $items): ?>

    <?php echo form_hidden($i.'[rowid]', $items['rowid']); ?>

    <tr>
        <td><?php echo form_input(array('name' => $i.'[qty]', 'value' => $items['qty'], 'maxlength' => 5, 'type' => 'text')); ?></td>
        <td>
            <?php echo $items['name']; ?>

            <?php if ($this->cart->has_options($items['rowid']) == TRUE): ?>

                <p>
                    <?php foreach ($this->cart->product_options($items['rowid']) as $option): ?>
                        <strong><?php echo $option_name; ?></strong> <?php echo $option_price; ?></td>
                    <?php endforeach; ?>
                </p>
            <?php endif; ?>

        </td>
        <td style="text-align:right"><?php echo $this->cart->format_number($items['price']); ?></td>
        <td style="text-align:right">${<?php echo $this->cart->format_number($items['subtotal']); ?>}</td>
    </tr>

<?php $i++; ?>

<?php endforeach; ?>

<tr>
    <td colspan="2"></td>
    <td class="right"><strong>Total</strong></td>
    <td class="right">${<?php echo $this->cart->format_number($this->cart->total()); ?>}</td>
</tr>

</table>

<p><?php echo form_submit('', 'Update your Cart'); ?></p>
```

Updating The Cart

To update the information in your cart, you must pass an array containing the Row ID and quantity to the `$this->cart->update()` function:

: If the quantity is set to zero, the item will be removed from the cart.

```
$data = array(
    'rowid' => 'b99ccdf16028f015540f341130b6d8ec',
    'qty'   => 3
);

$this->cart->update($data);

// Or a multi-dimensional array

$data = array(
    array(
        'rowid' => 'b99ccdf16028f015540f341130b6d8ec',
        'qty'   => 3
    ),
    array(
        'rowid' => 'xw82g9q3r495893iajdh473990rikw23',
        'qty'   => 4
    ),
    array(
        'rowid' => 'fh4kdkkkaoe30njgoe92rkdckobec333',
        'qty'   => 2
    )
);

$this->cart->update($data);
```

What is a Row ID?

The row ID is a unique identifier that is generated by the cart code when an item is added to the cart. The reason a unique ID is created is so that identical products with different options can be managed by the cart.

For example, let's say someone buys two identical t-shirts (same product ID), but in different sizes. The product ID (and other attributes) will be identical for both sizes because it's the same shirt. The only difference will be the size. The cart must therefore have a means of identifying this difference so that the two sizes of shirts can be managed independently. It does so by creating a unique "row ID" based on the product ID and any options associated with it.

In nearly all cases, updating the cart will be something the user does via the "view cart" page, so as a developer, it is unlikely that you will ever have to concern yourself with the "row ID", other than making sure your "view cart" page contains this information in a hidden form field, and making sure it gets passed to the update function when the update form is submitted. Please examine the construction of the "view cart" page above for more information.

Function Reference

`$this->cart->insert();`

Permits you to add items to the shopping cart, as outlined above.

`$this->cart->update();`

Permits you to update items in the shopping cart, as outlined above.

`$this->cart->remove(rowid);`

Allows you to remove an item from the shopping cart by passing it the rowid.

`$this->cart->total();`

Displays the total amount in the cart.

`$this->cart->total_items();`

Displays the total number of items in the cart.

`$this->cart->contents(boolean);`

Returns an array containing everything in the cart. You can sort the order, by which this is returned by passing it “true” where the contents will be sorted from newest to oldest, by leaving this function blank, you’ll automatically just get first added to the basket to last added to the basket.

`$this->cart->get_item($row_id);`

Returns an array containing data for the item matching the specified row ID, or FALSE if no such item exists.

`$this->cart->has_options($row_id);`

Returns TRUE (boolean) if a particular row in the cart contains options. This function is designed to be used in a loop with `$this->cart->contents()`, since you must pass the rowid to this function, as shown in the Displaying the Cart example above.

`$this->cart->product_options($row_id);`

Returns an array of options for a particular product. This function is designed to be used in a loop with `$this->cart->contents()`, since you must pass the rowid to this function, as shown in the Displaying the Cart example above.

`$this->cart->destroy();`

Permits you to destroy the cart. This function will likely be called when you are finished processing the customer’s order.

7.1.5 Config Class

The Config class provides a means to retrieve configuration preferences. These preferences can come from the default config file (application/config/config.php) or from your own custom config files.

: This class is initialized automatically by the system so there is no need to do it manually.

Page Contents

- Config Class
 - Anatomy of a Config File
 - Loading a Config File
 - * Manual Loading
 - * Auto-loading
 - Fetching Config Items
 - Setting a Config Item
 - Environments
 - Helper Functions
 - * `$this->config->site_url();`
 - * `$this->config->base_url();`
 - * `$this->config->system_url();`

Anatomy of a Config File

By default, CodeIgniter has one primary config file, located at application/config/config.php. If you open the file using your text editor you'll see that config items are stored in an array called `$config`.

You can add your own config items to this file, or if you prefer to keep your configuration items separate (assuming you even need config items), simply create your own file and save it in config folder.

: If you do create your own config files use the same format as the primary one, storing your items in an array called `$config`. CodeIgniter will intelligently manage these files so there will be no conflict even though the array has the same name (assuming an array index is not named the same as another).

Loading a Config File

: CodeIgniter automatically loads the primary config file (application/config/config.php), so you will only need to load a config file if you have created your own.

There are two ways to load a config file:

Manual Loading

To load one of your custom config files you will use the following function within the *controller* that needs it:

```
$this->config->load('filename');
```

Where filename is the name of your config file, without the .php file extension.

If you need to load multiple config files normally they will be merged into one master config array. Name collisions can occur, however, if you have identically named array indexes in different config files. To avoid collisions you can set the second parameter to TRUE and each config file will be stored in an array index corresponding to the name of the config file. Example:

```
// Stored in an array with this prototype: $this->config['blog_settings'] = $config
$this->config->load('blog_settings', TRUE);
```

Please see the section entitled Fetching Config Items below to learn how to retrieve config items set this way.

The third parameter allows you to suppress errors in the event that a config file does not exist:

```
$this->config->load('blog_settings', FALSE, TRUE);
```

Auto-loading

If you find that you need a particular config file globally, you can have it loaded automatically by the system. To do this, open the **autoload.php** file, located at application/config/autoload.php, and add your config file as indicated in the file.

Fetching Config Items

To retrieve an item from your config file, use the following function:

```
$this->config->item('item name');
```

Where item name is the \$config array index you want to retrieve. For example, to fetch your language choice you'll do this:

```
$lang = $this->config->item('language');
```

The function returns NULL if the item you are trying to fetch does not exist.

If you are using the second parameter of the \$this->config->load function in order to assign your config items to a specific index you can retrieve it by specifying the index name in the second parameter of the \$this->config->item() function. Example:

```
// Loads a config file named blog_settings.php and assigns it to an index named "blog_settings"
$this->config->load('blog_settings', TRUE);
```

```
// Retrieve a config item named site_name contained within the blog_settings array
$site_name = $this->config->item('site_name', 'blog_settings');
```

```
// An alternate way to specify the same item:
$blog_config = $this->config->item('blog_settings');
$site_name = $blog_config['site_name'];
```

Setting a Config Item

If you would like to dynamically set a config item or change an existing one, you can do so using:

```
$this->config->set_item('item_name', 'item_value');
```

Where item_name is the \$config array index you want to change, and item_value is its value.

Environments

You may load different configuration files depending on the current environment. The `ENVIRONMENT` constant is defined in `index.php`, and is described in detail in the *Handling Environments* section.

To create an environment-specific configuration file, create or copy a configuration file in `application/config/{ENVIRONMENT}/{FILENAME}.php`

For example, to create a production-only `config.php`, you would:

1. Create the directory `application/config/production/`
2. Copy your existing `config.php` into the above directory
3. Edit `application/config/production/config.php` so it contains your production settings

When you set the `ENVIRONMENT` constant to 'production', the settings for your new production-only `config.php` will be loaded.

You can place the following configuration files in environment-specific folders:

- Default CodeIgniter configuration files
- Your own custom configuration files

: CodeIgniter always loads the global config file first (i.e., the one in `application/config/`), then tries to load the configuration files for the current environment. This means you are not obligated to place **all** of your configuration files in an environment folder. Only the files that change per environment. Additionally you don't have to copy **all** the config items in the environment config file. Only the config items that you wish to change for your environment. The config items declared in your environment folders always overwrite those in your global config files.

Helper Functions

The config class has the following helper functions:

```
$this->config->site_url();
```

This function retrieves the URL to your site, along with the "index" value you've specified in the config file.

```
$this->config->base_url();
```

This function retrieves the URL to your site, plus an optional path such as to a stylesheet or image.

The two functions above are normally accessed via the corresponding functions in the *URL Helper*.

```
$this->config->system_url();
```

This function retrieves the URL to your system folder.

7.1.6 Email Class

CodeIgniter's robust Email Class supports the following features:

- Multiple Protocols: Mail, Sendmail, and SMTP

- TLS and SSL Encryption for SMTP
- Multiple recipients
- CC and BCCs
- HTML or Plaintext email
- Attachments
- Word wrapping
- Priorities
- BCC Batch Mode, enabling large email lists to be broken into small BCC batches.
- Email Debugging tools

Sending Email

Sending email is not only simple, but you can configure it on the fly or set your preferences in a config file.

Here is a basic example demonstrating how you might send email. Note: This example assumes you are sending the email from one of your *controllers*.

```
$this->load->library('email');

$this->email->from('your@example.com', 'Your Name');
$this->email->to('someone@example.com');
$this->email->cc('another@another-example.com');
$this->email->bcc('them@their-example.com');

$this->email->subject('Email Test');
$this->email->message('Testing the email class.');
```

```
$this->email->send();
```

Setting Email Preferences

There are 21 different preferences available to tailor how your email messages are sent. You can either set them manually as described here, or automatically via preferences stored in your config file, described below:

Preferences are set by passing an array of preference values to the email initialize method. Here is an example of how you might set some preferences:

```
$config['protocol'] = 'sendmail';
$config['mailpath'] = '/usr/sbin/sendmail';
$config['charset'] = 'iso-8859-1';
$config['wordwrap'] = TRUE;

$this->email->initialize($config);
```

: Most of the preferences have default values that will be used if you do not set them.

Setting Email Preferences in a Config File

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called the email.php, add the \$config array in that file. Then save the file at config/email.php and it will

be used automatically. You will NOT need to use the `$this->email->initialize()` method if you save your preferences in a config file.

Email Preferences

The following is a list of all the preferences that can be set when sending email.

Preference	Default Value	Options	Description
user-agent	CodeIgniter	None	The “user agent”.
protocol	mail	mail, sendmail, or smtp	The mail sending protocol.
mail-path	/usr/sbin/sendmail	None	The server path to Sendmail.
smtp_host	No Default	None	SMTP Server Address.
smtp_user	No Default	None	SMTP Username.
smtp_pass	No Default	None	SMTP Password.
smtp_port	25	None	SMTP Port.
smtp_timeout	5	None	SMTP Timeout (in seconds).
smtp_keepalive	FALSE	TRUE or FALSE (boolean)	Enable persistent SMTP connections.
smtp_crypto	No Default	tls or ssl	SMTP Encryption
word-wrap	TRUE	TRUE or FALSE (boolean)	Enable word-wrap.
wrapchars	76		Character count to wrap at.
mailtype	text	text or html	Type of mail. If you send HTML email you must send it as a complete web page. Make sure you don’t have any relative links or relative image paths otherwise they will not work.
charset	<code>\$config['charset']</code>		Character set (utf-8, iso-8859-1, etc.).
validate	FALSE	TRUE or FALSE (boolean)	Whether to validate the email address.
priority	3	1, 2, 3, 4, 5	Email Priority. 1 = highest. 5 = lowest. 3 = normal.
crlf	\n	“\r\n” or “\n” or “\r”	Newline character. (Use “\r\n” to comply with RFC 822).
newline	\n	“\r\n” or “\n” or “\r”	Newline character. (Use “\r\n” to comply with RFC 822).
bcc_batch_mode	FALSE	TRUE or FALSE (boolean)	Enable BCC Batch Mode.
bcc_batch_size	250	None	Number of emails in each BCC batch.
dsn	FALSE	TRUE or FALSE (boolean)	Enable notify message from server

Email Methods Reference

`$this->email->from()`

Sets the email address and name of the person sending the email:

```
$this->email->from('you@example.com', 'Your Name');
```

You can also set a Return-Path, to help redirect undelivered mail:

```
$this->email->from('you@example.com', 'Your Name', 'returned_emails@example.com');
```

: Return-Path can't be used if you've configured 'smtp' as your protocol.

`$this->email->reply_to()`

Sets the reply-to address. If the information is not provided the information in the “from” method is used. Example:

```
$this->email->reply_to('you@example.com', 'Your Name');
```

`$this->email->to()`

Sets the email address(s) of the recipient(s). Can be a single email, a comma-delimited list or an array:

```
$this->email->to('someone@example.com');
```

```
$this->email->to('one@example.com, two@example.com, three@example.com');
```

```
$list = array('one@example.com', 'two@example.com', 'three@example.com');
```

```
$this->email->to($list);
```

`$this->email->cc()`

Sets the CC email address(s). Just like the “to”, can be a single email, a comma-delimited list or an array.

`$this->email->bcc()`

Sets the BCC email address(s). Just like the “to”, can be a single email, a comma-delimited list or an array.

`$this->email->subject()`

Sets the email subject:

```
$this->email->subject('This is my subject');
```

`$this->email->message()`

Sets the email message body:

```
$this->email->message('This is my message');
```

`$this->email->set_alt_message()`

Sets the alternative email message body:

```
$this->email->set_alt_message('This is the alternative message');
```

This is an optional message string which can be used if you send HTML formatted email. It lets you specify an alternative message with no HTML formatting which is added to the header string for people who do not accept HTML email. If you do not set your own message CodeIgniter will extract the message from your HTML email and strip the tags.

`$this->email->set_header()`

Appends additional headers to the e-mail:

```
$this->email->set_header('Header1', 'Value1');
$this->email->set_header('Header2', 'Value2');
```

`$this->email->clear()`

Initializes all the email variables to an empty state. This method is intended for use if you run the email sending method in a loop, permitting the data to be reset between cycles.

```
foreach ($list as $name => $address)
{
    $this->email->clear();

    $this->email->to($address);
    $this->email->from('your@example.com');
    $this->email->subject('Here is your info '.$name);
    $this->email->message('Hi '.$name.' Here is the info you requested.');
```

If you set the parameter to TRUE any attachments will be cleared as well:

```
$this->email->clear(TRUE);
```

`$this->email->send()`

The Email sending method. Returns boolean TRUE or FALSE based on success or failure, enabling it to be used conditionally:

```
if ( ! $this->email->send() )
{
    // Generate error
}
```

This method will automatically clear all parameters if the request was successful. To stop this behaviour pass FALSE:

```
if ($this->email->send(FALSE))
{
    // Parameters won't be cleared
}
```

: In order to use the `print_debugger()` method, you need to avoid clearing the email parameters.

`$this->email->attach()`

Enables you to send an attachment. Put the file path/name in the first parameter. Note: Use a file path, not a URL. For multiple attachments use the method multiple times. For example:

```
$this->email->attach('/path/to/photo1.jpg');
$this->email->attach('/path/to/photo2.jpg');
$this->email->attach('/path/to/photo3.jpg');
```

To use the default disposition (attachment), leave the second parameter blank, otherwise use a custom disposition:

```
$this->email->attach('image.jpg', 'inline');
```

If you'd like to use a custom file name, you can use the third parameter:

```
$this->email->attach('filename.pdf', 'attachment', 'report.pdf');
```

If you need to use a buffer string instead of a real - physical - file you can use the first parameter as buffer, the third parameter as file name and the fourth parameter as mime-type:

```
$this->email->attach($buffer, 'attachment', 'report.pdf', 'application/pdf');
```

`$this->email->print_debugger()`

Returns a string containing any server messages, the email headers, and the email message. Useful for debugging.

You can optionally specify which parts of the message should be printed. Valid options are: **headers**, **subject**, **body**.

Example:

```
// You need to pass FALSE while sending in order for the email data
// to not be cleared - if that happens, print_debugger() would have
// nothing to output.
$this->email->send(FALSE);

// Will only print the email headers, excluding the message subject and body
$this->email->print_debugger(array('headers'));
```

: By default, all of the raw data will be printed.

Overriding Word Wrapping

If you have word wrapping enabled (recommended to comply with RFC 822) and you have a very long link in your email it can get wrapped too, causing it to become un-clickable by the person receiving it. CodeIgniter lets you manually override word wrapping within part of your message like this:

The text of your email that
gets wrapped normally.

```
{unwrap}http://example.com/a_long_link_that_should_not_be_wrapped.html{/unwrap}
```

More text that will be
wrapped normally.

Place the item you do not want word-wrapped between: {unwrap} {/unwrap}

7.1.7 Encryption Class

The Encryption Class provides two-way data encryption. It uses a scheme that either compiles the message using a randomly hashed bitwise XOR encoding scheme, or is encrypted using the Mcrypt library. If Mcrypt is not available on your server the encoded message will still provide a reasonable degree of security for encrypted sessions or other such “light” purposes. If Mcrypt is available, you’ll be provided with a high degree of security appropriate for storage.

Setting your Key

A *key* is a piece of information that controls the cryptographic process and permits an encrypted string to be decoded. In fact, the key you chose will provide the **only** means to decode data that was encrypted with that key, so not only must you choose the key carefully, you must never change it if you intend use it for persistent data.

It goes without saying that you should guard your key carefully. Should someone gain access to your key, the data will be easily decoded. If your server is not totally under your control it’s impossible to ensure key security so you may want to think carefully before using it for anything that requires high security, like storing credit card numbers.

To take maximum advantage of the encryption algorithm, your key should be 32 characters in length (256 bits). The key should be as random a string as you can concoct, with numbers and uppercase and lowercase letters. Your key should **not** be a simple text string. In order to be cryptographically secure it needs to be as random as possible.

Your key can be either stored in your **application/config/config.php**, or you can design your own storage mechanism and pass the key dynamically when encoding/decoding.

To save your key to your **application/config/config.php**, open the file and set:

```
$config['encryption_key'] = "YOUR KEY";
```

Message Length

It’s important for you to know that the encoded messages the encryption function generates will be approximately 2.6 times longer than the original message. For example, if you encrypt the string “my super secret data”, which is 21 characters in length, you’ll end up with an encoded string that is roughly 55 characters (we say “roughly” because the encoded string length increments in 64 bit clusters, so it’s not exactly linear). Keep this information in mind when selecting your data storage mechanism. Cookies, for example, can only hold 4K of information.

Initializing the Class

Like most other classes in CodeIgniter, the Encryption class is initialized in your controller using the **\$this->load->library** function:

```
$this->load->library('encrypt');
```

Once loaded, the Encrypt library object will be available using: **\$this->encrypt**

`$this->encrypt->encode()`

Performs the data encryption and returns it as a string. Example:

```
$msg = 'My secret message';

$encrypted_string = $this->encrypt->encode($msg);
```

You can optionally pass your encryption key via the second parameter if you don't want to use the one in your config file:

```
$msg = 'My secret message';
$key = 'super-secret-key';

$encrypted_string = $this->encrypt->encode($msg, $key);
```

`$this->encrypt->decode()`

Decrypts an encoded string. Example:

```
$encrypted_string = 'APAntByIGI1BpVXZTJgcsAG8GZl8pdwwa84';

$plaintext_string = $this->encrypt->decode($encrypted_string);
```

You can optionally pass your encryption key via the second parameter if you don't want to use the one in your config file:

```
$msg = 'My secret message';
$key = 'super-secret-key';

$encrypted_string = $this->encrypt->decode($msg, $key);
```

`$this->encrypt->set_cipher();`

Permits you to set an Mcrypt cipher. By default it uses **MCRYPT_RIJNDAEL_256**. Example:

```
$this->encrypt->set_cipher(MCRYPT_BLOWFISH);
```

Please visit php.net for a list of [available ciphers](#).

If you'd like to manually test whether your server supports Mcrypt you can use:

```
echo ( ! function_exists('mcrypt_encrypt')) ? 'Nope' : 'Yup';
```

`$this->encrypt->set_mode();`

Permits you to set an Mcrypt mode. By default it uses **MCRYPT_MODE_CBC**. Example:

```
$this->encrypt->set_mode(MCRYPT_MODE_CFB);
```

Please visit php.net for a list of [available modes](#).

```
$this->encrypt->encode_from_legacy($orig_data, $legacy_mode = MCRYPT_MODE_ECB, $key = '');
```

Enables you to re-encode data that was originally encrypted with CodeIgniter 1.x to be compatible with the Encryption library in CodeIgniter 2.x. It is only necessary to use this method if you have encrypted data stored permanently such as in a file or database and are on a server that supports Mcrypt. “Light” use encryption such as encrypted session data or transitory encrypted flashdata require no intervention on your part. However, existing encrypted Sessions will be destroyed since data encrypted prior to 2.x will not be decoded.

: Why only a method to re-encode the data instead of maintaining legacy methods for both encoding and decoding? The algorithms in the Encryption library have improved in CodeIgniter 2.x both for performance and security, and we do not wish to encourage continued use of the older methods. You can of course extend the Encryption library if you wish and replace the new methods with the old and retain seamless compatibility with CodeIgniter 1.x encrypted data, but this a decision that a developer should make cautiously and deliberately, if at all.

```
$new_data = $this->encrypt->encode_from_legacy($old_encrypted_string);
```

Parameter	Default	Description
<code>\$orig_data</code>	n/a	The original encrypted data from CodeIgniter 1.x’s Encryption library
<code>\$legacy_mode</code>	<code>MCRYPT_MODE_ECB</code>	The Mcrypt mode that was used to generate the original encrypted data. CodeIgniter 1.x’s default was <code>MCRYPT_MODE_ECB</code> , and it will assume that to be the case unless overridden by this parameter.
<code>\$key</code>	n/a	The encryption key. This it typically specified in your config file as outlined above.

7.1.8 File Uploading Class

CodeIgniter’s File Uploading Class permits files to be uploaded. You can set various preferences, restricting the type and size of the files.

The Process

Uploading a file involves the following general process:

- An upload form is displayed, allowing a user to select a file and upload it.
- When the form is submitted, the file is uploaded to the destination you specify.
- Along the way, the file is validated to make sure it is allowed to be uploaded based on the preferences you set.
- Once uploaded, the user will be shown a success message.

To demonstrate this process here is brief tutorial. Afterward you’ll find reference information.

Creating the Upload Form

Using a text editor, create a form called `upload_form.php`. In it, place this code and save it to your **application/views/** directory:

```
<html>
<head>
<title>Upload Form</title>
</head>
<body>
```

```

<?php echo $error;?>

<?php echo form_open_multipart('upload/do_upload');?>

<input type="file" name="userfile" size="20" />

<br /><br />

<input type="submit" value="upload" />

</form>

</body>
</html>

```

You'll notice we are using a form helper to create the opening form tag. File uploads require a multipart form, so the helper creates the proper syntax for you. You'll also notice we have an \$error variable. This is so we can show error messages in the event the user does something wrong.

The Success Page

Using a text editor, create a form called upload_success.php. In it, place this code and save it to your **application/views/** directory:

```

<html>
<head>
<title>Upload Form</title>
</head>
<body>

<h3>Your file was successfully uploaded!</h3>

<ul>
<?php foreach ($upload_data as $item => $value):?>
<li><?php echo $item;?: <?php echo $value;?></li>
<?php endforeach; ?>
</ul>

<p><?php echo anchor('upload', 'Upload Another File!'); ?></p>

</body>
</html>

```

The Controller

Using a text editor, create a controller called Upload.php. In it, place this code and save it to your **application/controllers/** directory:

```

<?php

class Upload extends CI_Controller {

    public function __construct()
    {
        parent::__construct();
    }
}

```

```
        $this->load->helper(array('form', 'url'));
    }

    public function index()
    {
        $this->load->view('upload_form', array('error' => ' ' ));
    }

    public function do_upload()
    {
        $config['upload_path']           = './uploads/';
        $config['allowed_types']         = 'gif|jpg|png';
        $config['max_size']               = 100;
        $config['max_width']              = 1024;
        $config['max_height']             = 768;

        $this->load->library('upload', $config);

        if ( ! $this->upload->do_upload())
        {
            $error = array('error' => $this->upload->display_errors());

            $this->load->view('upload_form', $error);
        }
        else
        {
            $data = array('upload_data' => $this->upload->data());

            $this->load->view('upload_success', $data);
        }
    }
}
?>
```

The Upload Directory

You'll need a destination directory for your uploaded images. Create a directory at the root of your CodeIgniter installation called uploads and set its file permissions to 777.

Try it!

To try your form, visit your site using a URL similar to this one:

`example.com/index.php/upload/`

You should see an upload form. Try uploading an image file (either a jpg, gif, or png). If the path in your controller is correct it should work.

Reference Guide

Initializing the Upload Class

Like most other classes in CodeIgniter, the Upload class is initialized in your controller using the `$this->load->library()` method:

```
$this->load->library('upload');
```

Once the Upload class is loaded, the object will be available using: `$this->upload`

Setting Preferences

Similar to other libraries, you'll control what is allowed to be upload based on your preferences. In the controller you built above you set the following preferences:

```
$config['upload_path'] = './uploads/';  
$config['allowed_types'] = 'gif|jpg|png';  
$config['max_size']     = '100';  
$config['max_width']    = '1024';  
$config['max_height']   = '768';
```

```
$this->load->library('upload', $config);
```

```
// Alternately you can set preferences by calling the ``initialize()`` method. Useful if you auto-load  
$this->upload->initialize($config);
```

The above preferences should be fairly self-explanatory. Below is a table describing all available preferences.

Preferences

The following preferences are available. The default value indicates what will be used if you do not specify that preference.

Preference	Default Value	Options	Description
upload_path	None	None	The path to the directory where the upload should be placed. The directory must be writable and the path can be absolute or relative.
allowed_types	None	None	The mime types corresponding to the types of files you allow to be uploaded. Usually the file extension can be used as the mime type. Separate multiple types with a pipe.
file_name	None	Desired file name	If set CodeIgniter will rename the uploaded file to this name. The extension provided in the file name must also be an allowed file type. If no extension is provided in the original file_name will be used.
file_ext_tolower	FALSE	TRUE/FALSE (boolean)	If set to TRUE, the file extension will be forced to lower case
overwrite	FALSE	TRUE/FALSE (boolean)	If set to true, if a file with the same name as the one you are uploading exists, it will be overwritten. If set to false, a number will be appended to the filename if another with the same name exists.
max_size	0	None	The maximum size (in kilobytes) that the file can be. Set to zero for no limit. Note: Most PHP installations have their own limit, as specified in the php.ini file. Usually 2 MB (or 2048 KB) by default.
max_width	0	None	The maximum width (in pixels) that the image can be. Set to zero for no limit.
max_height	0	None	The maximum height (in pixels) that the image can be. Set to zero for no limit.
min_width	0	None	The minimum width (in pixels) that the image can be. Set to zero for no limit.
min_height	0	None	The minimum height (in pixels) that the image can be. Set to zero for no limit.
max_filename	0	None	The maximum length that a file name can be. Set to zero for no limit.
max_filename_increment	100	None	When overwrite is set to FALSE, use this to set the maximum filename increment for CodeIgniter to append to the filename.
encrypt_name	FALSE	TRUE/FALSE (boolean)	If set to TRUE the file name will be converted to a random encrypted string. This can be useful if you would like the file saved with a name that can not be discerned by the person uploading it.
remove_spaces	TRUE	TRUE/FALSE (boolean)	If set to TRUE, any spaces in the file name will be converted to underscores. This is recommended.
detect_mime	TRUE	TRUE/FALSE (boolean)	If set to TRUE, a server side detection of the file type will be performed to avoid code injection attacks. DO NOT disable this option unless you have no other option as that would cause a security risk.
mod_mime_fix	TRUE	TRUE/FALSE (boolean)	If set to TRUE, multiple filename extensions will be suffixed with an underscore in order to avoid triggering Apache mod_mime . DO NOT turn off this option if your upload directory is public, as this is a security risk.

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called the upload.php, add the \$config array in that file. Then save the file in: **config/upload.php** and it will be used automatically. You will NOT need to use the `$this->upload->initialize()` method if you save your preferences in a config file.

Class Reference

The following methods are available:

`$this->upload->do_upload()`

Performs the upload based on the preferences you've set.

: By default the upload routine expects the file to come from a form field called `userfile`, and the form must be of type `"multipart"`.

```
<form method="post" action="some_action" enctype="multipart/form-data" />
```

If you would like to set your own field name simply pass its value to the `do_upload()` method:

```
$field_name = "some_field_name";
$this->upload->do_upload($field_name);
```

`$this->upload->display_errors()`

Retrieves any error messages if the `do_upload()` method returned false. The method does not echo automatically, it returns the data so you can assign it however you need.

Formatting Errors By default the above method wraps any errors within `<p>` tags. You can set your own delimiters like this:

```
$this->upload->display_errors(' <p>', ' </p>');
```

`$this->upload->data()`

This is a helper method that returns an array containing all of the data related to the file you uploaded. Here is the array prototype:

```
Array
(
    [file_name]      => mypic.jpg
    [file_type]      => image/jpeg
    [file_path]      => /path/to/your/upload/
    [full_path]      => /path/to/your/upload/jpg.jpg
    [raw_name]       => mypic
    [orig_name]      => mypic.jpg
    [client_name]    => mypic.jpg
    [file_ext]       => .jpg
    [file_size]      => 22.2
    [is_image]       => 1
    [image_width]    => 800
    [image_height]   => 600
    [image_type]     => jpeg
    [image_size_str] => width="800" height="200"
)
```

To return one element from the array:

```
$this->upload->data('file_name'); // Returns: mypic.jpg
```

Explanation Here is an explanation of the above array items.

Item Description **file_name** The name of the file that was uploaded including the file extension. **file_type** The file's Mime type **file_path** The absolute server path to the file **full_path** The absolute server path including the file name **raw_name** The file name without the extension **orig_name** The original file name. This is only useful if you use the encrypted name option. **client_name** The file name as supplied by the client user agent, prior to any file name preparation or incrementing. **file_ext** The file extension with period **file_size** The file size in kilobytes **is_image** Whether the file is an image or not. 1 = image. 0 = not. **image_width** Image width. **image_height** Image height **image_type** Image type. Typically the file extension without the period. **image_size_str** A string containing the width and height. Useful to put into an image tag.

7.1.9 Form Validation

CodeIgniter provides a comprehensive form validation and data prepping class that helps minimize the amount of code you'll write.

Overview

Before explaining CodeIgniter's approach to data validation, let's describe the ideal scenario:

1. A form is displayed.
2. You fill it in and submit it.
3. If you submitted something invalid, or perhaps missed a required item, the form is redisplayed containing your data along with an error message describing the problem.

4. This process continues until you have submitted a valid form.

On the receiving end, the script must:

1. Check for required data.
2. Verify that the data is of the correct type, and meets the correct criteria. For example, if a username is submitted it must be validated to contain only permitted characters. It must be of a minimum length, and not exceed a maximum length. The username can't be someone else's existing username, or perhaps even a reserved word. Etc.
3. Sanitize the data for security.
4. Pre-format the data if needed (Does the data need to be trimmed? HTML encoded? Etc.)
5. Prep the data for insertion in the database.

Although there is nothing terribly complex about the above process, it usually requires a significant amount of code, and to display error messages, various control structures are usually placed within the form HTML. Form validation, while simple to create, is generally very messy and tedious to implement.

Form Validation Tutorial

What follows is a “hands on” tutorial for implementing CodeIgniter's Form Validation.

In order to implement form validation you'll need three things:

1. A *View* file containing a form.
2. A *View* file containing a “success” message to be displayed upon successful submission.
3. A *controller* method to receive and process the submitted data.

Let's create those three things, using a member sign-up form as the example.

The Form

Using a text editor, create a form called `myform.php`. In it, place this code and save it to your `application/views/` folder:

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<?php echo validation_errors(); ?>

<?php echo form_open('form'); ?>

<h5>Username</h5>
<input type="text" name="username" value="" size="50" />

<h5>Password</h5>
<input type="text" name="password" value="" size="50" />

<h5>Password Confirm</h5>
<input type="text" name="passconf" value="" size="50" />

<h5>Email Address</h5>
<input type="text" name="email" value="" size="50" />
```

```
<div><input type="submit" value="Submit" /></div>

</form>

</body>
</html>
```

The Success Page

Using a text editor, create a form called `formsuccess.php`. In it, place this code and save it to your `application/views/` folder:

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<h3>Your form was successfully submitted!</h3>

<p><?php echo anchor('form', 'Try it again!'); ?></p>

</body>
</html>
```

The Controller

Using a text editor, create a controller called `form.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}
```

Try it!

To try your form, visit your site using a URL similar to this one:

`example.com/index.php/form/`

If you submit the form you should simply see the form reload. That's because you haven't set up any validation rules yet.

Since you haven't told the Form Validation class to validate anything yet, it returns FALSE (boolean false) by default. “The run()” method only returns TRUE if it has successfully applied your rules without any of them failing.

Explanation

You'll notice several things about the above pages:

The form (myform.php) is a standard web form with a couple exceptions:

1. It uses a form helper to create the form opening. Technically, this isn't necessary. You could create the form using standard HTML. However, the benefit of using the helper is that it generates the action URL for you, based on the URL in your config file. This makes your application more portable in the event your URLs change.
2. At the top of the form you'll notice the following function call:

```
<?php echo validation_errors(); ?>
```

This function will return any error messages sent back by the validator. If there are no messages it returns an empty string.

The controller (form.php) has one method: `index()`. This method initializes the validation class and loads the form helper and URL helper used by your view files. It also runs the validation routine. Based on whether the validation was successful it either presents the form or the success page.

Setting Validation Rules

CodeIgniter lets you set as many validation rules as you need for a given field, cascading them in order, and it even lets you prep and pre-process the field data at the same time. To set validation rules you will use the `set_rules()` method:

```
$this->form_validation->set_rules();
```

The above method takes **three** parameters as input:

1. The field name - the exact name you've given the form field.
2. A “human” name for this field, which will be inserted into the error message. For example, if your field is named “user” you might give it a human name of “Username”.
3. The validation rules for this form field.

: If you would like the field name to be stored in a language file, please see *Translating Field Names*.

Here is an example. In your controller (form.php), add this code just below the validation initialization method:

```
$this->form_validation->set_rules('username', 'Username', 'required');
$this->form_validation->set_rules('password', 'Password', 'required');
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
$this->form_validation->set_rules('email', 'Email', 'required');
```

Your controller should now look like this:

```

<?php

class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        $this->form_validation->set_rules('username', 'Username', 'required');
        $this->form_validation->set_rules('password', 'Password', 'required');
        $this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
        $this->form_validation->set_rules('email', 'Email', 'required');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}

```

Now submit the form with the fields blank and you should see the error messages. If you submit the form with all the fields populated you'll see your success page.

: The form fields are not yet being re-populated with the data when there is an error. We'll get to that shortly.

Setting Rules Using an Array

Before moving on it should be noted that the rule setting method can be passed an array if you prefer to set all your rules in one action. If you use this approach, you must name your array keys as indicated:

```

$config = array(
    array(
        'field' => 'username',
        'label' => 'Username',
        'rules' => 'required'
    ),
    array(
        'field' => 'password',
        'label' => 'Password',
        'rules' => 'required'
    ),
    array(
        'field' => 'passconf',
        'label' => 'Password Confirmation',
        'rules' => 'required'
    ),
    array(
        'field' => 'email',
        'label' => 'Email',
        'rules' => 'required'
    )
);

```

```
    )  
);  
  
$this->form_validation->set_rules($config);
```

Cascading Rules

CodeIgniter lets you pipe multiple rules together. Let's try it. Change your rules in the third parameter of rule setting method, like this:

```
$this->form_validation->set_rules('username', 'Username', 'required|min_length[5]|max_length[12]|is_unique[users.username]');  
$this->form_validation->set_rules('password', 'Password', 'required');  
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'required|matches[password]');  
$this->form_validation->set_rules('email', 'Email', 'required|valid_email|is_unique[users.email]');
```

The above code sets the following rules:

1. The username field be no shorter than 5 characters and no longer than 12.
2. The password field must match the password confirmation field.
3. The email field must contain a valid email address.

Give it a try! Submit your form without the proper data and you'll see new error messages that correspond to your new rules. There are numerous rules available which you can read about in the validation reference.

: You can also pass an array of rules to `set_rules()`, instead of a string. Example:

```
$this->form_validation->set_rules('username', 'Username', array('required', 'min_length[5]'));
```

Prepping Data

In addition to the validation method like the ones we used above, you can also prep your data in various ways. For example, you can set up rules like this:

```
$this->form_validation->set_rules('username', 'Username', 'trim|required|min_length[5]|max_length[12]|xss_clean');  
$this->form_validation->set_rules('password', 'Password', 'trim|required|md5');  
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'trim|required|matches[password]');  
$this->form_validation->set_rules('email', 'Email', 'trim|required|valid_email');
```

In the above example, we are “trimming” the fields, converting the password to MD5, and running the username through the `xss_clean()` method, which removes malicious data.

Any native PHP function that accepts one parameter can be used as a rule, like `htmlspecialchars`, `trim`, `md5`, etc.

: You will generally want to use the prepping functions **after** the validation rules so if there is an error, the original data will be shown in the form.

Re-populating the form

Thus far we have only been dealing with errors. It's time to repopulate the form field with the submitted data. CodeIgniter offers several helper functions that permit you to do this. The one you will use most commonly is:

```
set_value('field name')
```

Open your myform.php view file and update the **value** in each field using the `set_value()` function:

Don't forget to include each field name in the “`set_value()`” functions!

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<?php echo validation_errors(); ?>

<?php echo form_open('form'); ?>

<h5>Username</h5>
<input type="text" name="username" value="<?php echo set_value('username'); ?>" size="50" />

<h5>Password</h5>
<input type="text" name="password" value="<?php echo set_value('password'); ?>" size="50" />

<h5>Password Confirm</h5>
<input type="text" name="passconf" value="<?php echo set_value('passconf'); ?>" size="50" />

<h5>Email Address</h5>
<input type="text" name="email" value="<?php echo set_value('email'); ?>" size="50" />

<div><input type="submit" value="Submit" /></div>

</form>

</body>
</html>
```

Now reload your page and submit the form so that it triggers an error. Your form fields should now be re-populated

: The *Class Reference* section below contains functions that permit you to re-populate <select> menus, radio buttons, and checkboxes.

Important Note: If you use an array as the name of a form field, you must supply it as an array to the function. Example:

```
<input type="text" name="colors[]" value="<?php echo set_value('colors[]'); ?>" size="50" />
```

For more info please see the *Using Arrays as Field Names* section below.

Callbacks: Your own Validation Methods

The validation system supports callbacks to your own validation methods. This permits you to extend the validation class to meet your needs. For example, if you need to run a database query to see if the user is choosing a unique username, you can create a callback method that does that. Let's create an example of this.

In your controller, change the “username” rule to this:

```
$this->form_validation->set_rules('username', 'Username', 'callback_username_check');
```

Then add a new method called `username_check()` to your controller. Here's how your controller should now look:

```
<?php
```

```
class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        $this->form_validation->set_rules('username', 'Username', 'callback_username_check');
        $this->form_validation->set_rules('password', 'Password', 'required');
        $this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
        $this->form_validation->set_rules('email', 'Email', 'required|is_unique[users.email]');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }

    public function username_check($str)
    {
        if ($str == 'test')
        {
            $this->form_validation->set_message('username_check', 'The {field} field can');
            return FALSE;
        }
        else
        {
            return TRUE;
        }
    }
}
```

Reload your form and submit it with the word “test” as the username. You can see that the form field data was passed to your callback method for you to process.

To invoke a callback just put the method name in a rule, with “callback_” as the rule **prefix**. If you need to receive an extra parameter in your callback method, just add it normally after the method name between square brackets, as in: “callback_foo**[bar]**”, then it will be passed as the second argument of your callback method.

: You can also process the form data that is passed to your callback and return it. If your callback returns anything other than a boolean TRUE/FALSE it is assumed that the data is your newly processed form data.

Setting Error Messages

All of the native error messages are located in the following language file: **system/language/english/form_validation_lang.php**

To set your own custom message you can either edit that file, or use the following method:

```
$this->form_validation->set_message('rule', 'Error Message');
```

Where rule corresponds to the name of a particular rule, and Error Message is the text you would like displayed.

If you'd like to include a field's "human" name, or the optional parameter some rules allow for (such as max_length), you can add the **{field}** and **{param}** tags to your message, respectively:

```
$this->form_validation->set_message('min_length', '{field} must have at least {param} characters.');
```

On a field with the human name Username and a rule of min_length[5], an error would display: "Username must have at least 5 characters."

: The old *sprintf()* method of using *%s* in your error messages will still work, however it will override the tags above. You should use one or the other.

In the callback rule example above, the error message was set by passing the name of the method (without the "callback_" prefix):

```
$this->form_validation->set_message('username_check')
```

Translating Field Names

If you would like to store the "human" name you passed to the `set_rules()` method in a language file, and therefore make the name able to be translated, here's how:

First, prefix your "human" name with **lang:**, as in this example:

```
$this->form_validation->set_rules('first_name', 'lang:first_name', 'required');
```

Then, store the name in one of your language file arrays (without the prefix):

```
$lang['first_name'] = 'First Name';
```

: If you store your array item in a language file that is not loaded automatically by CI, you'll need to remember to load it in your controller using:

```
$this->lang->load('file_name');
```

See the *Language Class* page for more info regarding language files.

Changing the Error Delimiters

By default, the Form Validation class adds a paragraph tag (<p>) around each error message shown. You can either change these delimiters globally, individually, or change the defaults in a config file.

1. **Changing delimiters Globally** To globally change the error delimiters, in your controller method, just after loading the Form Validation class, add this:

```
$this->form_validation->set_error_delimiters('<div class="error">', '</div>');
```

In this example, we've switched to using div tags.

2. **Changing delimiters Individually** Each of the two error generating functions shown in this tutorial can be supplied their own delimiters as follows:

```
<?php echo form_error('field name', '<div class="error">', '</div>'); ?>
```

Or:

```
<?php echo validation_errors('<div class="error">', '</div>'); ?>
```

3. **Set delimiters in a config file** You can add your error delimiters in `application/config/form_validation.php` as follows:

```
$config['error_prefix'] = '<div class="error_prefix">';  
$config['error_suffix'] = '</div>';
```

Showing Errors Individually

If you prefer to show an error message next to each form field, rather than as a list, you can use the `form_error()` function.

Try it! Change your form so that it looks like this:

```
<h5>Username</h5>  
<?php echo form_error('username'); ?>  
<input type="text" name="username" value="<?php echo set_value('username'); ?>" size="50" />  
  
<h5>Password</h5>  
<?php echo form_error('password'); ?>  
<input type="text" name="password" value="<?php echo set_value('password'); ?>" size="50" />  
  
<h5>Password Confirm</h5>  
<?php echo form_error('passconf'); ?>  
<input type="text" name="passconf" value="<?php echo set_value('passconf'); ?>" size="50" />  
  
<h5>Email Address</h5>  
<?php echo form_error('email'); ?>  
<input type="text" name="email" value="<?php echo set_value('email'); ?>" size="50" />
```

If there are no errors, nothing will be shown. If there is an error, the message will appear.

: If you use an array as the name of a form field, you must supply it as an array to the function. Example:

```
<?php echo form_error('options[size]'); ?>  
<input type="text" name="options[size]" value="<?php echo set_value("options[size]"); ?>" size="50" />
```

For more info please see the *Using Arrays as Field Names* section below.

Validating an Array (other than `$_POST`)

Sometimes you may want to validate an array that does not originate from `$_POST` data.

In this case, you can specify the array to be validated:

```
$data = array(  
    'username' => 'johndoe',  
    'password' => 'mypassword',  
    'passconf' => 'mypassword'  
);
```

```
$this->form_validation->set_data($data);
```

Creating validation rules, running the validation, and retrieving error messages works the same whether you are validating `$_POST` data or an array.

: If you want to validate more than one array during a single execution, then you should call the `reset_validation()` method before setting up rules and validating the new array.

For more info please see the *Class Reference* section below.

Saving Sets of Validation Rules to a Config File

A nice feature of the Form Validation class is that it permits you to store all your validation rules for your entire application in a config file. You can organize these rules into “groups”. These groups can either be loaded automatically when a matching controller/method is called, or you can manually call each set as needed.

How to save your rules

To store your validation rules, simply create a file named `form_validation.php` in your `application/config/` folder. In that file you will place an array named `$config` with your rules. As shown earlier, the validation array will have this prototype:

```
$config = array(
    array(
        'field' => 'username',
        'label' => 'Username',
        'rules' => 'required'
    ),
    array(
        'field' => 'password',
        'label' => 'Password',
        'rules' => 'required'
    ),
    array(
        'field' => 'passconf',
        'label' => 'Password Confirmation',
        'rules' => 'required'
    ),
    array(
        'field' => 'email',
        'label' => 'Email',
        'rules' => 'required'
    )
);
```

Your validation rule file will be loaded automatically and used when you call the `run()` method.

Please note that you **MUST** name your `$config` array.

Creating Sets of Rules

In order to organize your rules into “sets” requires that you place them into “sub arrays”. Consider the following example, showing two sets of rules. We’ve arbitrarily called these two rules “signup” and “email”. You can name your rules anything you want:

```
$config = array(
    'signup' => array(
        array(
            'field' => 'username',
            'label' => 'Username',
            'rules' => 'required'
        ),
        array(
            'field' => 'password',
            'label' => 'Password',
            'rules' => 'required'
        ),
        array(
            'field' => 'passconf',
            'label' => 'Password Confirmation',
            'rules' => 'required'
        ),
        array(
            'field' => 'email',
            'label' => 'Email',
            'rules' => 'required'
        )
    ),
    'email' => array(
        array(
            'field' => 'emailaddress',
            'label' => 'EmailAddress',
            'rules' => 'required|valid_email'
        ),
        array(
            'field' => 'name',
            'label' => 'Name',
            'rules' => 'required|alpha'
        ),
        array(
            'field' => 'title',
            'label' => 'Title',
            'rules' => 'required'
        ),
        array(
            'field' => 'message',
            'label' => 'MessageBody',
            'rules' => 'required'
        )
    )
);
```

Calling a Specific Rule Group

In order to call a specific group, you will pass its name to the `run()` method. For example, to call the `signup` rule you will do this:

```
if ($this->form_validation->run('signup') == FALSE)
{
    $this->load->view('myform');
}
else
```

```
{
    $this->load->view('formsuccess');
}
```

Associating a Controller Method with a Rule Group

An alternate (and more automatic) method of calling a rule group is to name it according to the controller class/method you intend to use it with. For example, let's say you have a controller named Member and a method named signup. Here's what your class might look like:

```
<?php

class Member extends CI_Controller {

    public function signup()
    {
        $this->load->library('form_validation');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}
```

In your validation config file, you will name your rule group member/signup:

```
$config = array(
    'member/signup' => array(
        array(
            'field' => 'username',
            'label' => 'Username',
            'rules' => 'required'
        ),
        array(
            'field' => 'password',
            'label' => 'Password',
            'rules' => 'required'
        ),
        array(
            'field' => 'passconf',
            'label' => 'PasswordConfirmation',
            'rules' => 'required'
        ),
        array(
            'field' => 'email',
            'label' => 'Email',
            'rules' => 'required'
        )
    )
);
```

When a rule group is named identically to a controller class/method it will be used automatically when the `run()`

method is invoked from that class/method.

Using Arrays as Field Names

The Form Validation class supports the use of arrays as field names. Consider this example:

```
<input type="text" name="options[]" value="" size="50" />
```

If you do use an array as a field name, you must use the EXACT array name in the *Helper Functions* that require the field name, and as your Validation Rule field name.

For example, to set a rule for the above field you would use:

```
$this->form_validation->set_rules('options[]', 'Options', 'required');
```

Or, to show an error for the above field you would use:

```
<?php echo form_error('options[]'); ?>
```

Or to re-populate the field you would use:

```
<input type="text" name="options[]" value="<?php echo set_value('options[]'); ?>" size="50" />
```

You can use multidimensional arrays as field names as well. For example:

```
<input type="text" name="options[size]" value="" size="50" />
```

Or even:

```
<input type="text" name="sports[nba][basketball]" value="" size="50" />
```

As with our first example, you must use the exact array name in the helper functions:

```
<?php echo form_error('sports[nba][basketball]'); ?>
```

If you are using checkboxes (or other fields) that have multiple options, don't forget to leave an empty bracket after each option, so that all selections will be added to the POST array:

```
<input type="checkbox" name="options[]" value="red" />
<input type="checkbox" name="options[]" value="blue" />
<input type="checkbox" name="options[]" value="green" />
```

Or if you use a multidimensional array:

```
<input type="checkbox" name="options[color][]" value="red" />
<input type="checkbox" name="options[color][]" value="blue" />
<input type="checkbox" name="options[color][]" value="green" />
```

When you use a helper function you'll include the bracket as well:

```
<?php echo form_error('options[color][]'); ?>
```

Rule Reference

The following is a list of all the native rules that are available to use:

Rule	Parameter	Description	Example
required	No	Returns FALSE if the form element is empty.	
matches	Yes	Returns FALSE if the form element does not match the one in the parameter.	matches[form_item]
differs	Yes	Returns FALSE if the form element does not differ from the one in the parameter.	differs[form_item]
is_unique	Yes	Returns FALSE if the form element is not unique to the table and field name in the parameter. Note: This rule requires <i>Query Builder</i> to be enabled in order to work.	is_unique[table.field]
min_length	Yes	Returns FALSE if the form element is shorter than the parameter value.	min_length[3]
max_length	Yes	Returns FALSE if the form element is longer than the parameter value.	max_length[12]
exact_length	Yes	Returns FALSE if the form element is not exactly the parameter value.	exact_length[8]
greater_than	Yes	Returns FALSE if the form element is less than or equal to the parameter value or not numeric.	greater_than[8]
greater_than_equal_to	Yes	Returns FALSE if the form element is less than the parameter value, or not numeric.	greater_than_equal_to[8]
less_than	Yes	Returns FALSE if the form element is greater than or equal to the parameter value or not numeric.	less_than[8]
less_than_equal_to	Yes	Returns FALSE if the form element is greater than the parameter value, or not numeric.	less_than_equal_to[8]
alpha	No	Returns FALSE if the form element contains anything other than alphabetical characters.	
alpha_numeric	No	Returns FALSE if the form element contains anything other than alpha-numeric characters.	
alpha_numeric_spaces	No	Returns FALSE if the form element contains anything other than alpha-numeric characters or spaces. Should be used after trim to avoid spaces at the beginning or end.	
alpha_dash	No	Returns FALSE if the form element contains anything other than alpha-numeric characters, underscores or dashes.	
numeric	No	Returns FALSE if the form element contains anything other than numeric characters.	
integer	No	Returns FALSE if the form element contains anything other than an integer.	
decimal	No	Returns FALSE if the form element contains anything other than a decimal number.	
is_natural	No	Returns FALSE if the form element contains anything other than a natural number: 0, 1, 2, 3, etc.	
is_natural_no_zero	No	Returns FALSE if the form element contains anything other than a natural number, but not zero: 1, 2, 3, etc.	
valid_url	No	Returns FALSE if the form element does not contain a valid URL.	
valid_email	No	Returns FALSE if the form element does not contain a valid email address.	
valid_emails	No	Returns FALSE if any value provided in a comma separated list is not a valid email.	
valid_ip	No	Returns FALSE if the supplied IP is not valid. Accepts an optional parameter of 'ipv4' or 'ipv6' to specify an IP format.	
valid_base64	No	Returns FALSE if the supplied string contains anything other than valid Base64 characters.	

: These rules can also be called as discrete methods. For example:

```
$this->form_validation->required($string);
```

: You can also use any native PHP functions that permit up to two parameters, where at least one is required (to pass

the field data).

Prepping Reference

The following is a list of all the prepping methods that are available to use:

Name	Parameter	Description
xss_clean	No	Runs the data through the XSS filtering method, described in the <i>Security Class</i> page.
prep_for_form	No	Converts special characters so that HTML data can be shown in a form field without breaking it.
prep_url	No	Adds “http://” to URLs if missing.
strip_image_tags	No	Strips the HTML from image tags leaving the raw URL.
en-code_php_tags	No	Converts PHP tags to entities.

: You can also use any native PHP functions that permits one parameter, like `trim()`, `htmlspecialchars()`, `urldecode()`, etc.

Class Reference

class **Form_validation**

The following methods are intended for use in your controller.

`$this->form_validation->set_rules()`

```
Form_validation::set_rules($field, $label = '', $rules = '')
```

- **\$field** (*string*) – The field name
- **\$label** (*string*) – The field label
- **\$rules** (*mixed*) – The rules, as a string with rules separated by a pipe “|”, or an array or rules.

Object

Permits you to set validation rules, as described in the tutorial sections above:

- *Setting Validation Rules*
- *Saving Sets of Validation Rules to a Config File*

`$this->form_validation->run()`

```
Form_validation::run($group = '')
```

- **\$group** (*string*) – The name of the validation group to run

Boolean

Runs the validation routines. Returns boolean TRUE on success and FALSE on failure. You can optionally pass the name of the validation group via the method, as described in: *Saving Sets of Validation Rules to a Config File*

`$this->form_validation->set_message()`

```
Form_validation::set_message($lang, $val = '')
```

- **\$lang** (*string*) – The rule the message is for
- **\$val** (*string*) – The message

Object

Permits you to set custom error messages. See *Setting Error Messages*

`$this->form_validation->set_data()`

```
Form_validation::set_data($data = '')
```

- **\$data** (*array*) – The data to validate

Permits you to set an array for validation, instead of using the default `$_POST` array.

`$this->form_validation->reset_validation()`

```
Form_validation::reset_validation()
```

Permits you to reset the validation when you validate more than one array. This method should be called before validating each new array.

`$this->form_validation->error_array()`

```
Form_validation::error_array()
```

Array

Returns the error messages as an array.

Helper Reference

The following helper functions are available for use in the view files containing your forms. Note that these are procedural functions, so they **do not** require you to prepend them with `$this->form_validation`.

`form_error()`

Shows an individual error message associated with the field name supplied to the function. Example:

```
<?php echo form_error('username'); ?>
```

The error delimiters can be optionally specified. See the *Changing the Error Delimiters* section above.

validation_errors()

Shows all error messages as a string: Example:

```
<?php echo validation_errors(); ?>
```

The error delimiters can be optionally specified. See the *Changing the Error Delimiters* section above.

set_value()

Permits you to set the value of an input form or textarea. You must supply the field name via the first parameter of the function. The second (optional) parameter allows you to set a default value for the form. Example:

```
<input type="text" name="quantity" value="<?php echo set_value('quantity', '0'); ?>" size="50" />
```

The above form will show “0” when loaded for the first time.

set_select()

If you use a <select> menu, this function permits you to display the menu item that was selected. The first parameter must contain the name of the select menu, the second parameter must contain the value of each item, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<select name="myselect">
<option value="one" <?php echo set_select('myselect', 'one', TRUE); ?> >One</option>
<option value="two" <?php echo set_select('myselect', 'two'); ?> >Two</option>
<option value="three" <?php echo set_select('myselect', 'three'); ?> >Three</option>
</select>
```

set_checkbox()

Permits you to display a checkbox in the state it was submitted. The first parameter must contain the name of the checkbox, the second parameter must contain its value, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE). Example:

```
<input type="checkbox" name="mycheck[]" value="1" <?php echo set_checkbox('mycheck[]', '1'); ?> />
<input type="checkbox" name="mycheck[]" value="2" <?php echo set_checkbox('mycheck[]', '2'); ?> />
```

set_radio()

Permits you to display radio buttons in the state they were submitted. This function is identical to the **set_checkbox()** function above.

```
<input type="radio" name="myradio" value="1" <?php echo set_radio('myradio', '1', TRUE); ?> />
<input type="radio" name="myradio" value="2" <?php echo set_radio('myradio', '2'); ?> />
```

7.1.10 FTP Class

CodeIgniter's FTP Class permits files to be transferred to a remote server. Remote files can also be moved, renamed, and deleted. The FTP class also includes a "mirroring" function that permits an entire local directory to be recreated remotely via FTP.

: SFTP and SSL FTP protocols are not supported, only standard FTP.

Initializing the Class

Like most other classes in CodeIgniter, the FTP class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('ftp');
```

Once loaded, the FTP object will be available using: `$this->ftp`

Usage Examples

In this example a connection is opened to the FTP server, and a local file is read and uploaded in ASCII mode. The file permissions are set to 755.

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$this->ftp->upload('/local/path/to/myfile.html', '/public_html/myfile.html', 'ascii', 0775);

$this->ftp->close();
```

In this example a list of files is retrieved from the server.

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$list = $this->ftp->list_files('/public_html/');

print_r($list);

$this->ftp->close();
```

In this example a local directory is mirrored on the server.

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$this->ftp->mirror('/path/to/myfolder/', '/public_html/myfolder/');

$this->ftp->close();
```

Function Reference

\$this->ftp->connect()

Connects and logs into to the FTP server. Connection preferences are set by passing an array to the function, or you can store them in a config file.

Here is an example showing how you set preferences manually:

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['port']     = 21;
$config['passive']  = FALSE;
$config['debug']    = TRUE;

$this->ftp->connect($config);
```

Setting FTP Preferences in a Config File If you prefer you can store your FTP preferences in a config file. Simply create a new file called the ftp.php, add the \$config array in that file. Then save the file at config/ftp.php and it will be used automatically.

Available connection options

- **hostname** - the FTP hostname. Usually something like: ftp.example.com
- **username** - the FTP username.
- **password** - the FTP password.
- **port** - The port number. Set to 21 by default.
- **debug** - TRUE/FALSE (boolean). Whether to enable debugging to display error messages.
- **passive** - TRUE/FALSE (boolean). Whether to use passive mode. Passive is set automatically by default.

\$this->ftp->upload()

Uploads a file to your server. You must supply the local path and the remote path, and you can optionally set the mode and permissions. Example:

```
$this->ftp->upload('/local/path/to/myfile.html', '/public_html/myfile.html', 'ascii', 0775);
```

Mode options are: ascii, binary, and auto (the default). If auto is used it will base the mode on the file extension of the source file.

If set, permissions have to be passed as an octal value.

\$this->ftp->download()

Downloads a file from your server. You must supply the remote path and the local path, and you can optionally set the mode. Example:

```
$this->ftp->download('/public_html/myfile.html', '/local/path/to/myfile.html', 'ascii');
```

Mode options are: ascii, binary, and auto (the default). If auto is used it will base the mode on the file extension of the source file.

Returns FALSE if the download does not execute successfully (including if PHP does not have permission to write the local file)

\$this->ftp->rename()

Permits you to rename a file. Supply the source file name/path and the new file name/path.

```
// Renames green.html to blue.html
$this->ftp->rename('/public_html/foo/green.html', '/public_html/foo/blue.html');
```

\$this->ftp->move()

Lets you move a file. Supply the source and destination paths:

```
// Moves blog.html from "joe" to "fred"
$this->ftp->move('/public_html/joe/blog.html', '/public_html/fred/blog.html');
```

Note: if the destination file name is different the file will be renamed.

\$this->ftp->delete_file()

Lets you delete a file. Supply the source path with the file name.

```
$this->ftp->delete_file('/public_html/joe/blog.html');
```

\$this->ftp->delete_dir()

Lets you delete a directory and everything it contains. Supply the source path to the directory with a trailing slash.

Important Be VERY careful with this function. It will recursively delete **everything** within the supplied path, including sub-folders and all files. Make absolutely sure your path is correct. Try using the `list_files()` function first to verify that your path is correct.

```
$this->ftp->delete_dir('/public_html/path/to/folder/');
```

`$this->ftp->list_files()`

Permits you to retrieve a list of files on your server returned as an array. You must supply the path to the desired directory.

```
$list = $this->ftp->list_files('/public_html/');  
  
print_r($list);
```

`$this->ftp->mirror()`

Recursively reads a local folder and everything it contains (including sub-folders) and creates a mirror via FTP based on it. Whatever the directory structure of the original file path will be recreated on the server. You must supply a source path and a destination path:

```
$this->ftp->mirror('/path/to/myfolder/', '/public_html/myfolder/');
```

`$this->ftp->mkdir()`

Lets you create a directory on your server. Supply the path ending in the folder name you wish to create, with a trailing slash. Permissions can be set by passed an octal value in the second parameter (if you are running PHP 5).

```
// Creates a folder named "bar"  
$this->ftp->mkdir('/public_html/foo/bar/', DIR_WRITE_MODE);
```

`$this->ftp->chmod()`

Permits you to set file permissions. Supply the path to the file or folder you wish to alter permissions on:

```
// Chmod "bar" to 777  
$this->ftp->chmod('/public_html/foo/bar/', DIR_WRITE_MODE);
```

`$this->ftp->close();`

Closes the connection to your server. It's recommended that you use this when you are finished uploading.

7.1.11 Image Manipulation Class

CodeIgniter's Image Manipulation class lets you perform the following actions:

- Image Resizing
- Thumbnail Creation
- Image Cropping
- Image Rotating
- Image Watermarking

All three major image libraries are supported: GD/GD2, NetPBM, and ImageMagick

: Watermarking is only available using the GD/GD2 library. In addition, even though other libraries are supported, GD is required in order for the script to calculate the image properties. The image processing, however, will be performed with the library you specify.

Initializing the Class

Like most other classes in CodeIgniter, the image class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('image_lib');
```

Once the library is loaded it will be ready for use. The image library object you will use to call all functions is: `$this->image_lib`

Processing an Image

Regardless of the type of processing you would like to perform (resizing, cropping, rotation, or watermarking), the general process is identical. You will set some preferences corresponding to the action you intend to perform, then call one of four available processing functions. For example, to create an image thumbnail you'll do this:

```
$config['image_library'] = 'gd2';
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['create_thumb'] = TRUE;
$config['maintain_ratio'] = TRUE;
$config['width']         = 75;
$config['height']        = 50;
```

```
$this->load->library('image_lib', $config);
```

```
$this->image_lib->resize();
```

The above code tells the `image_resize` function to look for an image called *mypic.jpg* located in the `source_image` folder, then create a thumbnail that is 75 X 50 pixels using the GD2 `image_lib`. Since the `maintain_ratio` option is enabled, the thumb will be as close to the target width and height as possible while preserving the original aspect ratio. The thumbnail will be called *mypic_thumb.jpg*

: In order for the image class to be allowed to do any processing, the folder containing the image files must have write permissions.

: Image processing can require a considerable amount of server memory for some operations. If you are experiencing out of memory errors while processing images you may need to limit their maximum size, and/or adjust PHP memory limits.

Processing Functions

There are four available processing functions:

- `$this->image_lib->resize()`
- `$this->image_lib->crop()`

- `$this->image_lib->rotate()`
- `$this->image_lib->watermark()`
- `$this->image_lib->clear()`

These functions return boolean TRUE upon success and FALSE for failure. If they fail you can retrieve the error message using this function:

```
echo $this->image_lib->display_errors();
```

A good practice is use the processing function conditionally, showing an error upon failure, like this:

```
if ( ! $this->image_lib->resize() )
{
    echo $this->image_lib->display_errors();
}
```

: You can optionally specify the HTML formatting to be applied to the errors, by submitting the opening/closing tags in the function, like this:

```
$this->image_lib->display_errors(' <p>', ' </p>' );
```

Preferences

The preferences described below allow you to tailor the image processing to suit your needs.

Note that not all preferences are available for every function. For example, the x/y axis preferences are only available for image cropping. Likewise, the width and height preferences have no effect on cropping. The “availability” column indicates which functions support a given preference.

Availability Legend:

- R - Image Resizing
- C - Image Cropping
- X - Image Rotation
- W - Image Watermarking

Pref-er-ence	De-fault Value	Options	Description	Avail-ability
image_library	GD2	GD, GD2, ImageMagick, NetPBM	Sets the image library to be used.	R, C, X, W
library_path	None	None	Sets the server path to your ImageMagick or NetPBM library. If you use either of those libraries you must supply the path.	R, C, X R, C, S, W
source_image	None	None	Sets the source image name/path. The path must be a relative or absolute server path, not a URL.	
dynamic_output	FALSE	TRUE/FALSE (boolean)	Determines whether the new image file should be written to disk or generated dynamically. Note: If you choose the dynamic setting, only one image can be shown at a time, and it can't be positioned on the page. It simply outputs the raw image dynamically to your browser, along with image headers.	R, C, X, W
quality	90%	1 - 100%	Sets the quality of the image. The higher the quality the larger the file size.	R, C, X, W
new_image	None	None	Sets the destination image name/path. You'll use this preference when creating an image copy. The path must be a relative or absolute server path, not a URL.	R, C, X, W
width	None	None	Sets the width you would like the image set to.	R, C
height	None	None	Sets the height you would like the image set to.	R, C
create_thumb	FALSE	TRUE/FALSE (boolean)	Tells the image processing function to create a thumb.	R
thumb_marker	None	None	Specifies the thumbnail indicator. It will be inserted just before the file extension, so mypic.jpg would become mypic_thumb.jpg	R
maintain_ratio	TRUE	TRUE/FALSE (boolean)	Specifies whether to maintain the original aspect ratio when resizing or use hard values.	R, C
master_dim	auto	auto, width, height	Specifies what to use as the master axis when resizing or creating thumbs. For example, let's say you want to resize an image to 100 X 75 pixels. If the source image size does not allow perfect resizing to those dimensions, this setting determines which axis should be used as the hard value. "auto" sets the axis automatically based on whether the image is taller then wider, or vice versa.	R
rotation_angle	None	90, 180, 270, vrt, hor	Specifies the angle of rotation when rotating images. Note that PHP rotates counter-clockwise, so a 90 degree rotation to the right must be specified as 270.	X
x_axis	None	None	Sets the X coordinate in pixels for image cropping. For example, a setting of 30 will crop an image 30 pixels from the left.	C
y_axis	None	None	Sets the Y coordinate in pixels for image cropping. For example, a setting of 30 will crop an image 30 pixels from the top.	C

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called `image_lib.php`, add the `$config` array in that file. Then save the file in: `config/image_lib.php` and it will be used automatically. You will NOT need to use the `$this->image_lib->initialize` function if you save your preferences in a config file.

`$this->image_lib->resize()`

The image resizing function lets you resize the original image, create a copy (with or without resizing), or create a thumbnail image.

For practical purposes there is no difference between creating a copy and creating a thumbnail except a thumb will have the thumbnail marker as part of the name (ie, mypic_thumb.jpg).

All preferences listed in the table above are available for this function except these three: `rotation_angle`, `x_axis`, and `y_axis`.

Creating a Thumbnail The resizing function will create a thumbnail file (and preserve the original) if you set this preference to `TRUE`:

```
$config['create_thumb'] = TRUE;
```

This single preference determines whether a thumbnail is created or not.

Creating a Copy The resizing function will create a copy of the image file (and preserve the original) if you set a path and/or a new filename using this preference:

```
$config['new_image'] = '/path/to/new_image.jpg';
```

Notes regarding this preference:

- If only the new image name is specified it will be placed in the same folder as the original
- If only the path is specified, the new image will be placed in the destination with the same name as the original.
- If both the path and image name are specified it will placed in its own destination and given the new name.

Resizing the Original Image If neither of the two preferences listed above (`create_thumb`, and `new_image`) are used, the resizing function will instead target the original image for processing.

`$this->image_lib->crop()`

The cropping function works nearly identically to the resizing function except it requires that you set preferences for the X and Y axis (in pixels) specifying where to crop, like this:

```
$config['x_axis'] = '100';  
$config['y_axis'] = '40';
```

All preferences listed in the table above are available for this function except these: `rotation_angle`, `create_thumb`, `new_image`.

Here's an example showing how you might crop an image:

```
$config['image_library'] = 'imagemagick';  
$config['library_path'] = '/usr/X11R6/bin/';  
$config['source_image'] = '/path/to/image/mypic.jpg';  
$config['x_axis'] = '100';  
$config['y_axis'] = '60';  
  
$this->image_lib->initialize($config);  
  
if ( ! $this->image_lib->crop() )
```

```
{
    echo $this->image_lib->display_errors();
}
```

: Without a visual interface it is difficult to crop images, so this function is not very useful unless you intend to build such an interface. That's exactly what we did using for the photo gallery module in ExpressionEngine, the CMS we develop. We added a JavaScript UI that lets the cropping area be selected.

`$this->image_lib->rotate()`

The image rotation function requires that the angle of rotation be set via its preference:

```
$config['rotation_angle'] = '90';
```

There are 5 rotation options:

1. 90 - rotates counter-clockwise by 90 degrees.
2. 180 - rotates counter-clockwise by 180 degrees.
3. 270 - rotates counter-clockwise by 270 degrees.
4. hor - flips the image horizontally.
5. vrt - flips the image vertically.

Here's an example showing how you might rotate an image:

```
$config['image_library'] = 'netpbm';
$config['library_path'] = '/usr/bin/';
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['rotation_angle'] = 'hor';

$this->image_lib->initialize($config);

if ( ! $this->image_lib->rotate() )
{
    echo $this->image_lib->display_errors();
}
```

`$this->image_lib->clear()`

The clear function resets all of the values used when processing an image. You will want to call this if you are processing images in a loop.

```
$this->image_lib->clear();
```

Image Watermarking

The Watermarking feature requires the GD/GD2 library.

Two Types of Watermarking

There are two types of watermarking that you can use:

- **Text:** The watermark message will be generating using text, either with a True Type font that you specify, or using the native text output that the GD library supports. If you use the True Type version your GD installation must be compiled with True Type support (most are, but not all).
- **Overlay:** The watermark message will be generated by overlaying an image (usually a transparent PNG or GIF) containing your watermark over the source image.

Watermarking an Image

Just as with the other functions (resizing, cropping, and rotating) the general process for watermarking involves setting the preferences corresponding to the action you intend to perform, then calling the watermark function. Here is an example:

```
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['wm_text'] = 'Copyright 2006 - John Doe';
$config['wm_type'] = 'text';
$config['wm_font_path'] = './system/fonts/texb.ttf';
$config['wm_font_size'] = '16';
$config['wm_font_color'] = 'ffffff';
$config['wm_vrt_alignment'] = 'bottom';
$config['wm_hor_alignment'] = 'center';
$config['wm_padding'] = '20';

$this->image_lib->initialize($config);

$this->image_lib->watermark();
```

The above example will use a 16 pixel True Type font to create the text “Copyright 2006 - John Doe”. The watermark will be positioned at the bottom/center of the image, 20 pixels from the bottom of the image.

: In order for the image class to be allowed to do any processing, the image file must have “write” file permissions. For example, 777.

Watermarking Preferences

This table shown the preferences that are available for both types of watermarking (text or overlay)

Preference	Default Value	Options	Description
wm_type	text	text, overlay	Sets the type of watermarking that should be used.
source_image	None	None	Sets the source image name/path. The path must be a relative or absolute server path, not a URL.
dynamic_output	FALSE	TRUE/FALSE (boolean)	Determines whether the new image file should be written to disk or generated dynamically. Note: If you choose the dynamic setting, only one image can be shown at a time, and it can't be positioned on the page. It simply outputs the raw image dynamically to your browser, along with image headers.
quality	90%	1 - 100%	Sets the quality of the image. The higher the quality the larger the file size.
wm_padding	None	A number	The amount of padding, set in pixels, that will be applied to the watermark to set it away from the edge of your images.
wm_vrt_alignment	top	top, middle, bottom	Sets the vertical alignment for the watermark image.
wm_hor_alignment	center	left, center, right	Sets the horizontal alignment for the watermark image.
wm_hor_offset	None	None	You may specify a horizontal offset (in pixels) to apply to the watermark position. The offset normally moves the watermark to the right, except if you have your alignment set to "right" then your offset value will move the watermark toward the left of the image.
wm_vrt_offset	None	None	You may specify a vertical offset (in pixels) to apply to the watermark position. The offset normally moves the watermark down, except if you have your alignment set to "bottom" then your offset value will move the watermark toward the top of the image.

Text Preferences This table shown the preferences that are available for the text type of watermarking.

Preference	Default Value	Options	Description
wm_text	None	None	The text you would like shown as the watermark. Typically this will be a copyright notice.
wm_font_path	None	None	The server path to the True Type Font you would like to use. If you do not use this option, the native GD font will be used.
wm_font_size	16	None	The size of the text. Note: If you are not using the True Type option above, the number is set using a range of 1 - 5. Otherwise, you can use any valid pixel size for the font you're using.
wm_font_color	ffffff	None	The font color, specified in hex. Both the full 6-length (ie, 993300) and the short three character abbreviated version (ie, fff) are supported.
wm_shadow_color	None	None	The color of the drop shadow, specified in hex. If you leave this blank a drop shadow will not be used. Both the full 6-length (ie, 993300) and the short three character abbreviated version (ie, fff) are supported.
wm_shadow_distance	None	None	The distance (in pixels) from the font that the drop shadow should appear.

Overlay Preferences This table shown the preferences that are available for the overlay type of watermarking.

Preference	Default Value	Options	Description
wm_overlay	None	None	The server path to the image you wish to use as your watermark. Required only if you are using the overlay method.
wm_opacity	50	1 - 100	Image opacity. You may specify the opacity (i.e. transparency) of your watermark image. This allows the watermark to be faint and not completely obscure the details from the original image behind it. A 50% opacity is typical.
wm_x_transp		A number	If your watermark image is a PNG or GIF image, you may specify a color on the image to be “transparent”. This setting (along with the next) will allow you to specify that color. This works by specifying the “X” and “Y” coordinate pixel (measured from the upper left) within the image that corresponds to a pixel representative of the color you want to be transparent.
wm_y_transp		A number	Along with the previous setting, this allows you to specify the coordinate to a pixel representative of the color you want to be transparent.

7.1.12 Input Class

The Input Class serves two purposes:

1. It pre-processes global input data for security.
2. It provides some helper methods for fetching input data and pre-processing it.

: This class is initialized automatically by the system so there is no need to do it manually.

Security Filtering

The security filtering method is called automatically when a new *controller* is invoked. It does the following:

- If `$config['allow_get_array']` is FALSE (default is TRUE), destroys the global GET array.
- Destroys all global variables in the event `register_globals` is turned on.
- Filters the GET/POST/COOKIE array keys, permitting only alpha-numeric (and a few other) characters.
- Provides XSS (Cross-site Scripting Hacks) filtering. This can be enabled globally, or upon request.
- Standardizes newline characters to `\n` (In Windows `\r\n`)

XSS Filtering

The Input class has the ability to filter input automatically to prevent cross-site scripting attacks. If you want the filter to run automatically every time it encounters POST or COOKIE data you can enable it by opening your application/config/config.php file and setting this:

```
$config['global_xss_filtering'] = TRUE;
```

Please refer to the *Security class* documentation for information on using XSS Filtering in your application.

Using POST, GET, COOKIE, or SERVER Data

CodeIgniter comes with four helper methods that let you fetch POST, GET, COOKIE or SERVER items. The main advantage of using the provided methods rather than fetching an item directly (`$_POST['something']`) is that

the methods will check to see if the item is set and return NULL if not. This lets you conveniently use data without having to test whether an item exists first. In other words, normally you might do something like this:

```
$something = isset($_POST['something']) ? $_POST['something'] : NULL;
```

With CodeIgniter's built in methods you can simply do this:

```
$something = $this->input->post('something');
```

The four methods are:

- `$this->input->post()`
- `$this->input->get()`
- `$this->input->cookie()`
- `$this->input->server()`

`$this->input->post()`

The first parameter will contain the name of the POST item you are looking for:

```
$this->input->post('some_data');
```

The method returns NULL if the item you are attempting to retrieve does not exist.

The second optional parameter lets you run the data through the XSS filter. It's enabled by setting the second parameter to boolean TRUE;

```
$this->input->post('some_data', TRUE);
```

To return an array of all POST items call without any parameters.

To return all POST items and pass them through the XSS filter set the first parameter NULL while setting the second parameter to boolean;

The method returns NULL if there are no items in the POST.

```
$this->input->post(NULL, TRUE); // returns all POST items with XSS filter
$this->input->post(); // returns all POST items without XSS filter
```

`$this->input->get()`

This method is identical to the POST method, only it fetches GET data

```
$this->input->get('some_data', TRUE);
```

To return an array of all GET items call without any parameters.

To return all GET items and pass them through the XSS filter set the first parameter NULL while setting the second parameter to boolean;

The method returns NULL if there are no items in the GET.

```
$this->input->get(NULL, TRUE); // returns all GET items with XSS filter
$this->input->get(); // returns all GET items without XSS filtering
```

`$this->input->post_get()`

This method will search through both the POST and GET streams for data, looking first in POST, and then in GET:

```
$this->input->post_get('some_data', TRUE);
```

`$this->input->get_post()`

This method will search through both the POST and GET streams for data, looking first in GET, and then in POST:

```
$this->input->get_post('some_data', TRUE);
```

`$this->input->cookie()`

This method is identical to the POST method, only it fetches cookie data

```
$this->input->cookie('some_cookie');  
$this->input->cookie('some_cookie', TRUE); // with XSS filter
```

`$this->input->server()`

This method is identical to the above methods, only it fetches server data:

```
$this->input->server('some_data');
```

Using the `php://input` stream

If you want to utilize the PUT, DELETE, PATCH or other exotic request methods, they can only be accessed via a special input stream, that can only be read once. This isn't as easy as just reading from e.g. the `$_POST` array, because it will always exist and you can try and access multiple variables without caring that you might only have one shot at all of the POST data.

CodeIgniter will take care of that for you, and you can access data from the **`php://input`** stream at any time, just by calling the `input_stream()` method:

```
$this->input->input_stream('key');
```

Similar to the methods above, if the requested data is not found, it will return NULL and you can also decide whether to run the data through `xss_clean()` by passing a boolean value as the second parameter:

```
$this->input->input_stream('key', TRUE); // XSS Clean  
$this->input->input_stream('key', FALSE); // No XSS filter
```

: You can utilize `method()` in order to know if you're reading PUT, DELETE or PATCH data.

`$this->input->set_cookie()`

Sets a cookie containing the values you specify. There are two ways to pass information to this method so that a cookie can be set: Array Method, and Discrete Parameters:

Array Method

Using this method, an associative array is passed to the first parameter:

```
$cookie = array(
    'name'    => 'The Cookie Name',
    'value'   => 'The Value',
    'expire'  => '86500',
    'domain'  => '.some-domain.com',
    'path'    => '/',
    'prefix'  => 'myprefix_',
    'secure'  => TRUE
);

$this->input->set_cookie($cookie);
```

Notes:

Only the name and value are required. To delete a cookie set it with the expiration blank.

The expiration is set in **seconds**, which will be added to the current time. Do not include the time, but rather only the number of seconds from *now* that you wish the cookie to be valid. If the expiration is set to zero the cookie will only last as long as the browser is open.

For site-wide cookies regardless of how your site is requested, add your URL to the **domain** starting with a period, like this: `.your-domain.com`

The path is usually not needed since the method sets a root path.

The prefix is only needed if you need to avoid name collisions with other identically named cookies for your server.

The secure boolean is only needed if you want to make it a secure cookie by setting it to TRUE.

Discrete Parameters

If you prefer, you can set the cookie by passing data using individual parameters:

```
$this->input->set_cookie($name, $value, $expire, $domain, $path, $prefix, $secure);
```

`$this->input->ip_address()`

Returns the IP address for the current user. If the IP address is not valid, the method will return an IP of: 0.0.0.0

```
echo $this->input->ip_address();
```

`$this->input->valid_ip($ip)`

Takes an IP address as input and returns TRUE or FALSE (boolean) if it is valid or not.

: The `$this->input->ip_address()` method above automatically validates the IP address.

```
if ( ! $this->input->valid_ip($ip) )
{
    echo 'Not Valid';
}
else
```

```
{
    echo 'Valid';
}
```

Accepts an optional second string parameter of 'ipv4' or 'ipv6' to specify an IP format. The default checks for both formats.

`$this->input->user_agent()`

Returns the user agent (web browser) being used by the current user. Returns FALSE if it's not available.

```
echo $this->input->user_agent();
```

See the *User Agent Class* for methods which extract information from the user agent string.

`$this->input->request_headers()`

Useful if running in a non-Apache environment where `apache_request_headers()` will not be supported. Returns an array of headers.

```
$headers = $this->input->request_headers();
```

`$this->input->get_request_header()`

Returns a single member of the request headers array.

```
$this->input->get_request_header('some-header', TRUE);
```

`$this->input->is_ajax_request()`

Checks to see if the HTTP_X_REQUESTED_WITH server header has been set, and returns a boolean response.

`$this->input->is_cli_request()`

Checks to see if the STDIN constant is set, which is a failsafe way to see if PHP is being run on the command line.

```
$this->input->is_cli_request();
```

: This method is DEPRECATED and is now just an alias for the `is_cli()` function.

`$this->input->method()`

Returns the `$_SERVER['REQUEST_METHOD']`, optional set uppercase or lowercase (default lowercase).

```
echo $this->input->method(TRUE); // Outputs: POST
echo $this->input->method(FALSE); // Outputs: post
echo $this->input->method(); // Outputs: post
```

: This driver is experimental. Its feature set and implementation may change in future releases.

7.1.13 Javascript Class

CodeIgniter provides a library to help you with certain common functions that you may want to use with Javascript. Please note that CodeIgniter does not require the jQuery library to run, and that any scripting library will work equally well. The jQuery library is simply presented as a convenience if you choose to use it.

Initializing the Class

To initialize the Javascript class manually in your controller constructor, use the `$this->load->library` function. Currently, the only available library is jQuery, which will automatically be loaded like this:

```
$this->load->library('javascript');
```

The Javascript class also accepts parameters, `js_library_driver` (string) default 'jquery' and `autoload` (bool) default TRUE. You may override the defaults if you wish by sending an associative array:

```
$this->load->library('javascript', array('js_library_driver' => 'scripto', 'autoload' => FALSE));
```

Again, presently only 'jquery' is available. You may wish to set `autoload` to FALSE, though, if you do not want the jQuery library to automatically include a script tag for the main jQuery script file. This is useful if you are loading it from a location outside of CodeIgniter, or already have the script tag in your markup.

Once loaded, the jQuery library object will be available using: `$this->javascript`

Setup and Configuration

Set these variables in your view

As a Javascript library, your files must be available to your application.

As Javascript is a client side language, the library must be able to write content into your final output. This generally means a view. You'll need to include the following variables in the `<head>` sections of your output.

```
<?php echo $library_src;?>
<?php echo $script_head;?>
```

`$library_src`, is where the actual library file will be loaded, as well as any subsequent plugin script calls; `$script_head` is where specific events, functions and other commands will be rendered.

Set the path to the libraries with config items

There are some configuration items in Javascript library. These can either be set in `application/config.php`, within its own `config/javascript.php` file, or within any controller using the `set_item()` function.

An image to be used as an "ajax loader", or progress indicator. Without one, the simple text message of "loading" will appear when Ajax calls need to be made.

```
$config['javascript_location'] = 'http://localhost/codeigniter/themes/js/jquery/';
$config['javascript_ajax_img'] = 'images/ajax-loader.gif';
```

If you keep your files in the same directories they were downloaded from, then you need not set this configuration items.

The jQuery Class

To initialize the jQuery class manually in your controller constructor, use the `$this->load->library` function:

```
$this->load->library('javascript/jquery');
```

You may send an optional parameter to determine whether or not a script tag for the main jQuery file will be automatically included when loading the library. It will be created by default. To prevent this, load the library as follows:

```
$this->load->library('javascript/jquery', FALSE);
```

Once loaded, the jQuery library object will be available using: `$this->jquery`

jQuery Events

Events are set using the following syntax.

```
$this->jquery->event('element_path', code_to_run());
```

In the above example:

- “event” is any of blur, change, click, dblclick, error, focus, hover, keydown, keyup, load, mousedown, mouseup, mouseover, mouseup, resize, scroll, or unload.
- “element_path” is any valid [jQuery selector](#). Due to jQuery’s unique selector syntax, this is usually an element id, or CSS selector. For example “#notice_area” would effect `<div id=“notice_area”>`, and “#content a.notice” would effect all anchors with a class of “notice” in the div with id “content”.
- “code_to_run()” is script your write yourself, or an action such as an effect from the jQuery library below.

Effects

The query library supports a powerful [Effects](#) repertoire. Before an effect can be used, it must be loaded:

```
$this->jquery->effect([optional path] plugin name); // for example $this->jquery->effect('bounce');
```

hide() / show()

Each of this functions will affect the visibility of an item on your page. `hide()` will set an item invisible, `show()` will reveal it.

```
$this->jquery->hide(target, optional speed, optional extra information);  
$this->jquery->show(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

toggle()

`toggle()` will change the visibility of an item to the opposite of its current state, hiding visible elements, and revealing hidden ones.

```
$this->jquery->toggle(target);
```

- “target” will be any valid jQuery selector or selectors.

animate()

```
$this->jquery->animate(target, parameters, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “parameters” in jQuery would generally include a series of CSS properties that you wish to change.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

For a full summary, see <http://docs.jquery.com/Effects/animate>

Here is an example of an `animate()` called on a div with an id of “note”, and triggered by a click using the jQuery library’s `click()` event.

```
$params = array(
    'height' => 80,
    'width' => '50%',
    'marginLeft' => 125
);
$this->jquery->click('#trigger', $this->jquery->animate('#note', $params, 'normal'));
```

fadeIn() / fadeOut()

```
$this->jquery->fadeIn(target, optional speed, optional extra information);
$this->jquery->fadeOut(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

toggleClass()

This function will add or remove a CSS class to its target.

```
$this->jquery->toggleClass(target, class)
```

- “target” will be any valid jQuery selector or selectors.
- “class” is any CSS classname. Note that this class must be defined and available in a CSS that is already loaded.

fadeIn() / fadeOut()

These effects cause an element(s) to disappear or reappear over time.

```
$this->jquery->fadeIn(target, optional speed, optional extra information);
$this->jquery->fadeOut(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

slideUp() / slideDown() / slideToggle()

These effects cause an element(s) to slide.

```
$this->jquery->slideUp(target, optional speed, optional extra information);  
$this->jquery->slideDown(target, optional speed, optional extra information);  
$this->jquery->slideToggle(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

Plugins

Some select jQuery plugins are made available using this library.

corner()

Used to add distinct corners to page elements. For full details see <http://www.malsup.com/jquery/corner/>

```
$this->jquery->corner(target, corner_style);
```

- “target” will be any valid jQuery selector or selectors.
- “corner_style” is optional, and can be set to any valid style such as round, sharp, bevel, bite, dog, etc. Individual corners can be set by following the style with a space and using “tl” (top left), “tr” (top right), “bl” (bottom left), or “br” (bottom right).

```
$this->jquery->corner("#note", "cool tl br");
```

7.1.14 Language Class

The Language Class provides functions to retrieve language files and lines of text for purposes of internationalization.

In your CodeIgniter system folder you'll find one called `language` containing sets of language files. You can create your own language files as needed in order to display error and other messages in other languages.

Language files are typically stored in your **system/language/** directory. Alternately you can create a directory called `language` inside your application folder and store them there. CodeIgniter will always load the one in **system/language/** first and will then look for an override in your **application/language/** directory.

: Each language should be stored in its own folder. For example, the English files are located at: `system/language/english`

Creating Language Files

Language files must be named with **_lang.php** as the file extension. For example, let's say you want to create a file containing error messages. You might name it: `error_lang.php`

Within the file you will assign each line of text to an array called `$lang` with this prototype:

```
$lang['language_key'] = 'The actual message to be shown';
```

: It's a good practice to use a common prefix for all messages in a given file to avoid collisions with similarly named items in other files. For example, if you are creating error messages you might prefix them with `error_`

```
$lang['error_email_missing'] = 'You must submit an email address';
$lang['error_url_missing'] = 'You must submit a URL';
$lang['error_username_missing'] = 'You must submit a username';
```

Loading A Language File

In order to fetch a line from a particular file you must load the file first. Loading a language file is done with the following code:

```
$this->lang->load('filename', 'language');
```

Where `filename` is the name of the file you wish to load (without the file extension), and `language` is the language set containing it (ie, english). If the second parameter is missing, the default language set in your **application/config/config.php** file will be used.

: The *language* parameter can only consist of letters.

Fetching a Line of Text

Once your desired language file is loaded you can access any line of text using this function:

```
$this->lang->line('language_key');
```

Where *language_key* is the array key corresponding to the line you wish to show.

You can optionally pass `FALSE` as the second argument of that method to disable error logging, in case you're not sure if the line exists:

```
$this->lang->line('misc_key', FALSE);
```

: This method simply returns the line. It does not echo it.

Using language lines as form labels

This feature has been deprecated from the language library and moved to the `lang()` function of the *Language Helper*.

Auto-loading Languages

If you find that you need a particular language globally throughout your application, you can tell CodeIgniter to *auto-load* it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the language(s) to the autoload array.

7.1.15 Loader Class

Loader, as the name suggests, is used to load elements. These elements can be libraries (classes) *View files*, *Drivers*, *Helpers*, *Models*, or your own files.

: This class is initialized automatically by the system so there is no need to do it manually.

The following methods are available in this class:

`$this->load->library('class_name', $config, 'object name')`

This method is used to load core classes. Where `class_name` is the name of the class you want to load.

: We use the terms “class” and “library” interchangeably.

For example, if you would like to send email with CodeIgniter, the first step is to load the email class within your controller:

```
$this->load->library('email');
```

Once loaded, the library will be ready for use, using `$this->email->*some_method*()`.

Library files can be stored in subdirectories within the main “libraries” directory, or within your personal application/libraries directory. To load a file located in a subdirectory, simply include the path, relative to the “libraries” directory. For example, if you have file located at:

```
libraries/flavors/Chocolate.php
```

You will load it using:

```
$this->load->library('flavors/chocolate');
```

You may nest the file in as many subdirectories as you want.

Additionally, multiple libraries can be loaded at the same time by passing an array of libraries to the load method.

```
$this->load->library(array('email', 'table'));
```

Setting options

The second (optional) parameter allows you to optionally pass configuration setting. You will typically pass these as an array:

```
$config = array (
    'mailtype' => 'html',
    'charset'  => 'utf-8',
    'priority' => '1'
);

$this->load->library('email', $config);
```

Config options can usually also be set via a config file. Each library is explained in detail in its own page, so please read the information regarding each one you would like to use.

Please take note, when multiple libraries are supplied in an array for the first parameter, each will receive the same parameter information.

Assigning a Library to a different object name

If the third (optional) parameter is blank, the library will usually be assigned to an object with the same name as the library. For example, if the library is named Calendar, it will be assigned to a variable named `$this->calendar`.

If you prefer to set your own class names you can pass its value to the third parameter:

```
$this->load->library('calendar', '', 'my_calendar');

// Calendar class is now accessed using:
$this->my_calendar
```

Please take note, when multiple libraries are supplied in an array for the first parameter, this parameter is discarded.

`$this->load->driver('parent_name', $config, 'object name')`

This method is used to load driver libraries. Where `parent_name` is the name of the parent class you want to load.

As an example, if you would like to use sessions with CodeIgniter, the first step is to load the session driver within your controller:

```
$this->load->driver('session');
```

Once loaded, the library will be ready for use, using `$this->session->*some_method*()`.

Driver files must be stored in a subdirectory within the main “libraries” directory, or within your personal application/libraries directory. The subdirectory must match the parent class name. Read the *Drivers* description for details.

Additionally, multiple driver libraries can be loaded at the same time by passing an array of drivers to the load method.

```
$this->load->driver(array('session', 'cache'));
```

Setting options

The second (optional) parameter allows you to optionally pass configuration settings. You will typically pass these as an array:

```
$config = array(
    'sess_driver' => 'cookie',
    'sess_encrypt_cookie' => true,
    'encryption_key' => 'mysecretkey'
);

$this->load->driver('session', $config);
```

Config options can usually also be set via a config file. Each library is explained in detail in its own page, so please read the information regarding each one you would like to use.

Assigning a Driver to a different object name

If the third (optional) parameter is blank, the library will be assigned to an object with the same name as the parent class. For example, if the library is named Session, it will be assigned to a variable named `$this->session`.

If you prefer to set your own class names you can pass its value to the third parameter:

```
$this->load->library('session', '', 'my_session');

// Session class is now accessed using:
$this->my_session
```

: Driver libraries may also be loaded with the `library()` method, but it is faster to use `driver()`.

`$this->load->view('file_name', $data, TRUE/FALSE)`

This method is used to load your View files. If you haven't read the *Views* section of the user guide it is recommended that you do since it shows you how this method is typically used.

The first parameter is required. It is the name of the view file you would like to load.

: The `.php` file extension does not need to be specified unless you use something other than `.php`.

The second **optional** parameter can take an associative array or an object as input, which it runs through the PHP `extract()` function to convert to variables that can be used in your view files. Again, read the *Views* page to learn how this might be useful.

The third **optional** parameter lets you change the behavior of the method so that it returns data as a string rather than sending it to your browser. This can be useful if you want to process the data in some way. If you set the parameter to `true` (boolean) it will return data. The default behavior is `false`, which sends it to your browser. Remember to assign it to a variable if you want the data returned:

```
$string = $this->load->view('myfile', '', true);
```

`$this->load->model('model_name');`

```
$this->load->model('model_name');
```

If your model is located in a subdirectory, include the relative path from your models directory. For example, if you have a model located at `application/models/blog/Queries.php` you'll load it using:

```
$this->load->model('blog/queries');
```

If you would like your model assigned to a different object name you can specify it via the second parameter of the loading method:

```
$this->load->model('model_name', 'fubar');  
$this->fubar->method();
```

`$this->load->database('options', TRUE/FALSE)`

This method lets you load the database class. The two parameters are **optional**. Please see the *database* section for more info.

`$this->load->vars($array)`

This method takes an associative array as input and generates variables using the PHP `extract` method. This method produces the same result as using the second parameter of the `$this->load->view()` method above. The reason you might want to use this method independently is if you would like to set some global variables in the constructor of your controller and have them become available in any view file loaded from any method. You can have multiple calls to this method. The data gets cached and merged into one array for conversion to variables.

`$this->load->get_var($key)`

This method checks the associative array of variables available to your views. This is useful if for any reason a var is set in a library or another controller method using `$this->load->vars()`.

`$this->load->get_vars()`

This method retrieves all variables available to your views.

`$this->load->clear_vars()`

Clears cached view variables.

`$this->load->helper('file_name')`

This method loads helper files, where `file_name` is the name of the file, without the `_helper.php` extension.

`$this->load->file('filepath/filename', TRUE/FALSE)`

This is a generic file loading method. Supply the filepath and name in the first parameter and it will open and read the file. By default the data is sent to your browser, just like a View file, but if you set the second parameter to true (boolean) it will instead return the data as a string.

`$this->load->language('file_name')`

This method is an alias of the *language loading method*: `$this->lang->load()`

`$this->load->config('file_name')`

This method is an alias of the *config file loading method*: `$this->config->load()`

`$this->load->is_loaded('library_name')`

The `is_loaded()` method allows you to check if a class has already been loaded or not.

: The word “class” here refers to libraries and drivers.

If the requested class has been loaded, the method returns its assigned name in the CI Super-object and FALSE if it's not:

```
$this->load->library('form_validation');  
$this->load->is_loaded('Form_validation');      // returns 'form_validation'  
  
$this->load->is_loaded('Nonexistent_library');   // returns FALSE
```

: If you have more than one instance of a class (assigned to different properties), then the first one will be returned.

```
$this->load->library('form_validation', $config, 'fv');  
$this->load->library('form_validation');  
  
$this->load->is_loaded('Form_validation');      // returns 'fv'
```

Application “Packages”

An application package allows for the easy distribution of complete sets of resources in a single directory, complete with its own libraries, models, helpers, config, and language files. It is recommended that these packages be placed in the `application/third_party` directory. Below is a sample map of an package directory

Sample Package “Foo Bar” Directory Map

The following is an example of a directory for an application package named “Foo Bar”.

```
/application/third_party/foo_bar  
  
config/  
helpers/  
language/  
libraries/  
models/
```

Whatever the purpose of the “Foo Bar” application package, it has its own config files, helpers, language files, libraries, and models. To use these resources in your controllers, you first need to tell the Loader that you are going to be loading resources from a package, by adding the package path.

`$this->load->add_package_path()`

Adding a package path instructs the Loader class to prepend a given path for subsequent requests for resources. As an example, the “Foo Bar” application package above has a library named Foo_bar.php. In our controller, we’d do the following:

```
$this->load->add_package_path(APPPATH.'third_party/foo_bar/');
$this->load->library('foo_bar');
```

`$this->load->remove_package_path()`

When your controller is finished using resources from an application package, and particularly if you have other application packages you want to work with, you may wish to remove the package path so the Loader no longer looks in that directory for resources. To remove the last path added, simply call the method with no parameters.

`$this->load->remove_package_path()`

Or to remove a specific package path, specify the same path previously given to `add_package_path()` for a package.:

```
$this->load->remove_package_path(APPPATH.'third_party/foo_bar/');
```

Package view files

By Default, package view files paths are set when `add_package_path()` is called. View paths are looped through, and once a match is encountered that view is loaded.

In this instance, it is possible for view naming collisions within packages to occur, and possibly the incorrect package being loaded. To ensure against this, set an optional second parameter of `FALSE` when calling `add_package_path()`.

```
$this->load->add_package_path(APPPATH.'my_app', FALSE);
$this->load->view('my_app_index'); // Loads
$this->load->view('welcome_message'); // Will not load the default welcome_message b/c the second parameter is FALSE

// Reset things
$this->load->remove_package_path(APPPATH.'my_app');

// Again without the second parameter:
$this->load->add_package_path(APPPATH.'my_app');
$this->load->view('my_app_index'); // Loads
$this->load->view('welcome_message'); // Loads
```

7.1.16 Migrations Class

Migrations are a convenient way for you to alter your database in a structured and organized manner. You could edit fragments of SQL by hand but you would then be responsible for telling other developers that they need to go and run them. You would also have to keep track of which changes need to be run against the production machines next time you deploy.

The database table **migration** tracks which migrations have already been run so all you have to do is update your application files and call `$this->migration->current()` to work out which migrations should be run. The current version is found in `config/migration.php`.

Migration file names

Each Migration is run in numeric order forward or backwards depending on the method taken. Two numbering styles are available:

- **Sequential:** each migration is numbered in sequence, starting with **001**. Each number must be three digits, and there must not be any gaps in the sequence. (This was the numbering scheme prior to CodeIgniter 3.0.)
- **Timestamp:** each migration is numbered using the timestamp when the migration was created, in **YYYYM-MDDHHIIS** format (e.g. **20121031100537**). This helps prevent numbering conflicts when working in a team environment, and is the preferred scheme in CodeIgniter 3.0 and later.

The desired style may be selected using the `$config['migration_type']` setting in your **migration.php** config file.

Regardless of which numbering style you choose to use, prefix your migration files with the migration number followed by an underscore and a descriptive name for the migration. For example:

- **001_add_blog.php** (sequential numbering)
- **20121031100537_add_blog.php** (timestamp numbering)

Create a Migration

This will be the first migration for a new site which has a blog. All migrations go in the folder **application/migrations/** and have names such as **20121031100537_add_blog.php**:

```
<?php

defined('BASEPATH') OR exit('No direct script access allowed');

class Migration_Add_blog extends CI_Migration {

    public function up()
    {
        $this->dbforge->add_field(array(
            'blog_id' => array(
                'type' => 'INT',
                'constraint' => 5,
                'unsigned' => TRUE,
                'auto_increment' => TRUE
            ),
            'blog_title' => array(
                'type' => 'VARCHAR',
                'constraint' => '100',
            ),
            'blog_description' => array(
                'type' => 'TEXT',
                'null' => TRUE,
            ),
        ));
        $this->dbforge->add_key('blog_id', TRUE);
        $this->dbforge->create_table('blog');
    }

    public function down()
    {
        $this->dbforge->drop_table('blog');
    }

}
```

Then in **application/config/migration.php** set `$config['migration_version'] = 1;`.

Usage Example

In this example some simple code is placed in **application/controllers/Migrate.php** to update the schema.:

```
<?php

class Migrate extends CI_Controller
{
    public function index()
    {
        $this->load->library('migration');

        if ($this->migration->current() === FALSE)
        {
            show_error($this->migration->error_string());
        }
    }
}
```

Function Reference

`$this->migration->current()`

The current migration is whatever is set for `$config['migration_version']` in **application/config/migration.php**.

`$this->migration->error_string()`

This returns a string of errors while performing a migration.

`$this->migration->find_migrations()`

An array of migration filenames are returned that are found in the **migration_path** property.

`$this->migration->latest()`

This works much the same way as `current()` but instead of looking for the `$config['migration_version']` the Migration class will use the very newest migration found in the filesystem.

`$this->migration->version()`

Version can be used to roll back changes or step forwards programmatically to specific versions. It works just like `current` but ignores `$config['migration_version']`.:

```
$this->load->library('migration');
```

```
$this->migration->version(5);
```

Migration Preferences

The following is a table of all the config options for migrations.

Preference	Default	Options	Description
migration_enabled	FALSE	TRUE / FALSE	Enable or disable migrations.
migration_path	APP-PATH.'migrations/'	None	The path to your migrations folder.
migration_version	0	None	The current version your database should use.
migration_table	migrations	None	The table name for storing the schema version number.
migration_auto_latest	FALSE	TRUE / FALSE	Enable or disable automatically running migrations.
migration_type	'timestamp'	'timestamp' / 'sequential'	The type of numeric identifier used to name migration files.

7.1.17 Output Class

The Output class is a small class with one main function: To send the finalized web page to the requesting browser. It is also responsible for *caching* your web pages, if you use that feature.

: This class is initialized automatically by the system so there is no need to do it manually.

Under normal circumstances you won't even notice the Output class since it works transparently without your intervention. For example, when you use the *Loader* class to load a view file, it's automatically passed to the Output class, which will be called automatically by CodeIgniter at the end of system execution. It is possible, however, for you to manually intervene with the output if you need to, using either of the two following functions:

`$this->output->set_output();`

Permits you to manually set the final output string. Usage example:

```
$this->output->set_output($data);
```

: If you do set your output manually, it must be the last thing done in the function you call it from. For example, if you build a page in one of your controller functions, don't set the output until the end.

`$this->output->set_content_type();`

Permits you to set the mime-type of your page so you can serve JSON data, JPEG's, XML, etc easily.

```
$this->output
    ->set_content_type('application/json')
    ->set_output(json_encode(array('foo' => 'bar')));

$this->output
    ->set_content_type('jpeg') // You could also use ".jpeg" which will have the full stop removed by
    ->set_output(file_get_contents('files/something.jpg'));
```

: Make sure any non-mime string you pass to this method exists in config/mimes.php or it will have no effect.

You can also set the character set of the document, by passing a second argument:

```
$this->output->set_content_type('css', 'utf-8');
```

`$this->output->get_content_type()`

Returns the Content-Type HTTP header that's currently in use, excluding the character set value.

```
$mime = $this->output->get_content_type();
```

: If not set, the default return value is 'text/html'.

`$this->output->get_header()`

Gets the requested HTTP header value, if set.

If the header is not set, NULL will be returned. If an empty value is passed to the method, it will return FALSE.

Example:

```
$this->output->set_content_type('text/plain', 'UTF-8');
echo $this->output->get_header('content-type');
// Outputs: text/plain; charset=utf-8
```

: The header name is compared in a case-insensitive manner.

: Raw headers sent via PHP's native `header()` function are also detected.

`$this->output->get_output()`

Permits you to manually retrieve any output that has been sent for storage in the output class. Usage example:

```
$string = $this->output->get_output();
```

Note that data will only be retrievable from this function if it has been previously sent to the output class by one of the CodeIgniter functions like `$this->load->view()`.

`$this->output->append_output();`

Appends data onto the output string. Usage example:

```
$this->output->append_output($data);
```

`$this->output->set_header();`

Permits you to manually set server headers, which the output class will send for you when outputting the final rendered display. Example:

```
$this->output->set_header("HTTP/1.0 200 OK");
$this->output->set_header("HTTP/1.1 200 OK");
$this->output->set_header('Last-Modified: '.gmdate('D, d M Y H:i:s', $last_update).' GMT');
$this->output->set_header("Cache-Control: no-store, no-cache, must-revalidate");
$this->output->set_header("Cache-Control: post-check=0, pre-check=0");
$this->output->set_header("Pragma: no-cache");
```

`$this->output->set_status_header(code, 'text');`

Permits you to manually set a server status header. Example:

```
$this->output->set_status_header('401');
// Sets the header as: Unauthorized
```

See [here](#) for a full list of headers.

: This method is an alias for *Common function* `set_status_header()`.

`$this->output->enable_profiler();`

Permits you to enable/disable the *Profiler*, which will display benchmark and other data at the bottom of your pages for debugging and optimization purposes.

To enable the profiler place the following function anywhere within your *Controller* functions:

```
$this->output->enable_profiler(TRUE);
```

When enabled a report will be generated and inserted at the bottom of your pages.

To disable the profiler you will use:

```
$this->output->enable_profiler(FALSE);
```

`$this->output->set_profiler_sections();`

Permits you to enable/disable specific sections of the Profiler when enabled. Please refer to the *Profiler* documentation for further information.

`$this->output->cache();`

The CodeIgniter output library also controls caching. For more information, please see the *caching documentation*.

Parsing Execution Variables

CodeIgniter will parse the pseudo-variables {elapsed_time} and {memory_usage} in your output by default. To disable this, set the `$parse_exec_vars` class property to `FALSE` in your controller.

```
$this->output->parse_exec_vars = FALSE;
```

7.1.18 Pagination Class

CodeIgniter's Pagination class is very easy to use, and it is 100% customizable, either dynamically or via stored preferences.

If you are not familiar with the term “pagination”, it refers to links that allows you to navigate from page to page, like this:

```
« First < 1 2 3 4 5 > Last »
```

Example

Here is a simple example showing how to create pagination in one of your *controller* functions:

```
$this->load->library('pagination');

$config['base_url'] = 'http://example.com/index.php/test/page/';
$config['total_rows'] = 200;
$config['per_page'] = 20;

$this->pagination->initialize($config);

echo $this->pagination->create_links();
```

Notes

The `$config` array contains your configuration variables. It is passed to the `$this->pagination->initialize` function as shown above. Although there are some twenty items you can configure, at minimum you need the three shown. Here is a description of what those items represent:

- **base_url** This is the full URL to the controller class/function containing your pagination. In the example above, it is pointing to a controller called “Test” and a function called “page”. Keep in mind that you can *re-route your URI* if you need a different structure.
- **total_rows** This number represents the total rows in the result set you are creating pagination for. Typically this number will be the total rows that your database query returned.
- **per_page** The number of items you intend to show per page. In the above example, you would be showing 20 items per page.

The `create_links()` function returns an empty string when there is no pagination to show.

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called `pagination.php`, add the `$config` array in that file. Then save the file in: `config/pagination.php` and it will be used automatically. You will NOT need to use the `$this->pagination->initialize` function if you save your preferences in a config file.

Customizing the Pagination

The following is a list of all the preferences you can pass to the initialization function to tailor the display.

```
$config['uri_segment'] = 3;
```

The pagination function automatically determines which segment of your URI contains the page number. If you need something different you can specify it.

```
$config['num_links'] = 2;
```

The number of “digit” links you would like before and after the selected page number. For example, the number 2 will place two digits on either side, as in the example links at the very top of this page.

```
$config['use_page_numbers'] = TRUE;
```

By default, the URI segment will use the starting index for the items you are paginating. If you prefer to show the actual page number, set this to TRUE.

```
$config['page_query_string'] = TRUE;
```

By default, the pagination library assume you are using *URI Segments*, and constructs your links something like

```
http://example.com/index.php/test/page/20
```

If you have `$config['enable_query_strings']` set to TRUE your links will automatically be re-written using Query Strings. This option can also be explicitly set. Using `$config['page_query_string']` set to TRUE, the pagination link will become.

```
http://example.com/index.php?c=test&m=page&per_page=20
```

Note that “per_page” is the default query string passed, however can be configured using `$config['query_string_segment'] = 'your_string'`

```
$config['reuse_query_string'] = FALSE;
```

By default your Query String arguments (nothing to do with other query string options) will be ignored. Setting this config to TRUE will add existing query string arguments back into the URL after the URI segment and before the suffix

```
http://example.com/index.php/test/page/20?query=search%term
```

This helps you mix together normal *URI Segments* as well as query string arguments, which until 3.0 was not possible.

```
$config['prefix'] = '';
```

A custom prefix added to the path. The prefix value will be right before the offset segment.

```
$config['suffix'] = '';
```

A custom suffix added to the path. The suffix value will be right after the offset segment.

Adding Enclosing Markup

If you would like to surround the entire pagination with some markup you can do it with these two prefs:

```
$config['full_tag_open'] = '<p>';
```

The opening tag placed on the left side of the entire result.

```
$config['full_tag_close'] = '</p>';
```

The closing tag placed on the right side of the entire result.

Customizing the First Link

```
$config['first_link'] = 'First';
```

The text you would like shown in the “first” link on the left. If you do not want this link rendered, you can set its value to FALSE.

```
$config['first_tag_open'] = '<div>';
```

The opening tag for the “first” link.

```
$config['first_tag_close'] = '</div>';
```

The closing tag for the “first” link.

Customizing the Last Link

```
$config['last_link'] = 'Last';
```

The text you would like shown in the “last” link on the right. If you do not want this link rendered, you can set its value to FALSE.

```
$config['last_tag_open'] = '<div>';
```

The opening tag for the “last” link.

```
$config['last_tag_close'] = '</div>';
```

The closing tag for the “last” link.

Customizing the “Next” Link

```
$config['next_link'] = '&gt;';
```

The text you would like shown in the “next” page link. If you do not want this link rendered, you can set its value to FALSE.

```
$config['next_tag_open'] = '<div>';
```

The opening tag for the “next” link.

```
$config['next_tag_close'] = '</div>';
```

The closing tag for the “next” link.

Customizing the “Previous” Link

```
$config['prev_link'] = '&lt;';
```

The text you would like shown in the “previous” page link. If you do not want this link rendered, you can set its value to FALSE.

```
$config['prev_tag_open'] = '<div>';
```

The opening tag for the “previous” link.

```
$config['prev_tag_close'] = '</div>';
```

The closing tag for the “previous” link.

Customizing the “Current Page” Link

```
$config['cur_tag_open'] = '<b>';
```

The opening tag for the “current” link.

```
$config['cur_tag_close'] = '</b>';
```

The closing tag for the “current” link.

Customizing the “Digit” Link

```
$config['num_tag_open'] = '<div>';
```

The opening tag for the “digit” link.

```
$config['num_tag_close'] = '</div>';
```

The closing tag for the “digit” link.

Hiding the Pages

If you wanted to not list the specific pages (for example, you only want “next” and “previous” links), you can suppress their rendering by adding:

```
$config['display_pages'] = FALSE;
```

Adding attributes to anchors

If you want to add an extra attribute to be added to every link rendered by the pagination class, you can set them as key/value pairs in the “attributes” config

```
// Produces: class="myclass"
$config['attributes'] = array('class' => 'myclass');
```

: Usage of the old method of setting classes via “anchor_class” is deprecated.

Disabling the “rel” attribute

By default the rel attribute is dynamically generated and appended to the appropriate anchors. If for some reason you want to turn it off, you can pass boolean FALSE as a regular attribute

```
$config['attributes']['rel'] = FALSE;
```

7.1.19 Template Parser Class

The Template Parser Class enables you to parse pseudo-variables contained within your view files. It can parse simple variables or variable tag pairs. If you’ve never used a template engine, pseudo-variables look like this:

```
<html>
<head>
<title>{blog_title}</title>
</head>
<body>

<h3>{blog_heading}</h3>

{blog_entries}
<h5>{title}</h5>
<p>{body}</p>
{/blog_entries}
</body>
</html>
```

These variables are not actual PHP variables, but rather plain text representations that allow you to eliminate PHP from your templates (view files).

: CodeIgniter does **not** require you to use this class since using pure PHP in your view pages lets them run a little

faster. However, some developers prefer to use a template engine if they work with designers who they feel would find some confusion working with PHP.

: The Template Parser Class is **not** a full-blown template parsing solution. We've kept it very lean on purpose in order to maintain maximum performance.

Initializing the Class

Like most other classes in CodeIgniter, the Parser class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('parser');
```

Once loaded, the Parser library object will be available using: `$this->parser`

The following functions are available in this library:

`$this->parser->parse()`

This method accepts a template name and data array as input, and it generates a parsed version. Example:

```
$this->load->library('parser');

$data = array(
    'blog_title' => 'My Blog Title',
    'blog_heading' => 'My Blog Heading'
);

$this->parser->parse('blog_template', $data);
```

The first parameter contains the name of the *view file* (in this example the file would be called `blog_template.php`), and the second parameter contains an associative array of data to be replaced in the template. In the above example, the template would contain two variables: `{blog_title}` and `{blog_heading}`

There is no need to “echo” or do something with the data returned by `$this->parser->parse()`. It is automatically passed to the output class to be sent to the browser. However, if you do want the data returned instead of sent to the output class you can pass `TRUE` (boolean) to the third parameter:

```
$string = $this->parser->parse('blog_template', $data, TRUE);
```

`$this->parser->parse_string()`

This method works exactly like `parse()`, only accepts a string as the first parameter in place of a view file.

Variable Pairs

The above example code allows simple variables to be replaced. What if you would like an entire block of variables to be repeated, with each iteration containing new values? Consider the template example we showed at the top of the page:

```

<html>
<head>
<title>{blog_title}</title>
</head>
<body>

<h3>{blog_heading}</h3>

{blog_entries}
<h5>{title}</h5>
<p>{body}</p>
{/blog_entries}
</body>
</html>

```

In the above code you'll notice a pair of variables: {blog_entries} data... {/blog_entries}. In a case like this, the entire chunk of data between these pairs would be repeated multiple times, corresponding to the number of rows in a result.

Parsing variable pairs is done using the identical code shown above to parse single variables, except, you will add a multi-dimensional array corresponding to your variable pair data. Consider this example:

```

$this->load->library('parser');

$data = array(
    'blog_title'    => 'My Blog Title',
    'blog_heading'  => 'My Blog Heading',
    'blog_entries' => array(
        array('title' => 'Title 1', 'body' => 'Body 1'),
        array('title' => 'Title 2', 'body' => 'Body 2'),
        array('title' => 'Title 3', 'body' => 'Body 3'),
        array('title' => 'Title 4', 'body' => 'Body 4'),
        array('title' => 'Title 5', 'body' => 'Body 5')
    )
);

$this->parser->parse('blog_template', $data);

```

If your “pair” data is coming from a database result, which is already a multi-dimensional array, you can simply use the database result_array() function:

```

$query = $this->db->query("SELECT * FROM blog");

$this->load->library('parser');

$data = array(
    'blog_title'    => 'My Blog Title',
    'blog_heading'  => 'My Blog Heading',
    'blog_entries' => $query->result_array()
);

$this->parser->parse('blog_template', $data);

```

7.1.20 Security Class

The Security Class contains methods that help you create a secure application, processing input data for security.

XSS Filtering

CodeIgniter comes with a Cross Site Scripting Hack prevention filter which can either run automatically to filter all POST and COOKIE data that is encountered, or you can run it on a per item basis. By default it does **not** run globally since it requires a bit of processing overhead, and since you may not need it in all cases.

The XSS filter looks for commonly used techniques to trigger Javascript or other types of code that attempt to hijack cookies or do other malicious things. If anything disallowed is encountered it is rendered safe by converting the data to character entities.

Note: This function should only be used to deal with data upon submission. It's not something that should be used for general runtime processing since it requires a fair amount of processing overhead.

To filter data through the XSS filter use this function:

`$this->security->xss_clean()`

Here is an usage example:

```
$data = $this->security->xss_clean($data);
```

If you want the filter to run automatically every time it encounters POST or COOKIE data you can enable it by opening your application/config/config.php file and setting this:

```
$config['global_xss_filtering'] = TRUE;
```

Note: If you use the form validation class, it gives you the option of XSS filtering as well.

An optional second parameter, `is_image`, allows this function to be used to test images for potential XSS attacks, useful for file upload security. When this second parameter is set to TRUE, instead of returning an altered string, the function returns TRUE if the image is safe, and FALSE if it contained potentially malicious information that a browser may attempt to execute.

```
if ($this->security->xss_clean($file, TRUE) === FALSE)
{
    // file failed the XSS test
}
```

`$this->security->sanitize_filename()`

When accepting filenames from user input, it is best to sanitize them to prevent directory traversal and other security related issues. To do so, use the `sanitize_filename()` method of the Security class. Here is an example:

```
$filename = $this->security->sanitize_filename($this->input->post('filename'));
```

If it is acceptable for the user input to include relative paths, e.g. `file/in/some/approved/folder.txt`, you can set the second optional parameter, `$relative_path` to TRUE.

```
$filename = $this->security->sanitize_filename($this->input->post('filename'), TRUE);
```

Cross-site request forgery (CSRF)

You can enable CSRF protection by opening your application/config/config.php file and setting this:

```
$config['csrf_protection'] = TRUE;
```

If you use the *form helper*, then `form_open()` will automatically insert a hidden csrf field in your forms. If not, then you can use `csrf_get_token_name()` and `csrf_get_hash()`

```
$csrf = array(
    'name' => $this->security->csrf_get_token_name(),
    'hash' => $this->security->csrf_get_hash()
);

...

<input type="hidden" name="<?=$csrf['name'];?>" value="<?=$csrf['hash'];?>" />
```

Tokens may be either regenerated on every submission (default) or kept the same throughout the life of the CSRF cookie. The default regeneration of tokens provides stricter security, but may result in usability concerns as other tokens become invalid (back/forward navigation, multiple tabs/windows, asynchronous actions, etc). You may alter this behavior by editing the following config parameter

```
$config['csrf_regeneration'] = TRUE;
```

Select URIs can be whitelisted from csrf protection (for example API endpoints expecting externally POSTed content). You can add these URIs by editing the 'csrf_exclude_uris' config parameter:

```
$config['csrf_exclude_uris'] = array('api/person/add');
```

`$this->security->get_csrf_token_name()`

Returns the CSRF token name, which is set by `$config['csrf_token_name']`.

`$this->security->get_csrf_hash()`

Returns the CSRF hash value. Useful in combination with `get_csrf_token_name()` for manually building forms or sending valid AJAX POST requests.

7.1.21 Session Driver

The Session class permits you maintain a user's "state" and track their activity while they browse your site. CodeIgniter offers two default session drivers: the classic Cookie Driver, and the Native Driver, which supports usage of the native PHP Session mechanism. In addition, you may create your own Custom Drivers to store session data however you wish, while still taking advantage of the features of the Session class.

Initializing a Session

Sessions will typically run globally with each page load, so the session class must either be *initialized* in your *controller* constructors, or it can be *auto-loaded* by the system. For the most part the session class will run unattended in the background, so simply initializing the class will cause it to read, create, and update sessions.

To initialize the Session class manually in your controller constructor, use the `$this->load->driver` function:

```
$this->load->driver('session');
```

Once loaded, the Sessions library object will be available using: `$this->session`

How do Sessions work?

When a page is loaded, the session class will check to see if valid session data exists in the user's session. If sessions data does **not** exist (or if it has expired) a new session will be created and saved. If a session does exist, its information will be updated. With each update, the session_id will be regenerated.

It's important for you to understand that once initialized, the Session class runs automatically. There is nothing you need to do to cause the above behavior to happen. You can, as you'll see below, work with session data or even add your own data to a user's session, but the process of reading, writing, and updating a session is automatic.

What is Session Data?

A *session*, as far as CodeIgniter is concerned, is simply an array containing the following information:

- The user's unique Session ID (this is a statistically random string with very strong entropy, hashed with MD5 for portability, and regenerated (by default) every five minutes)
- The user's IP Address
- The user's User Agent data (the first 120 characters of the browser data string)
- The "last activity" time stamp.

The above data is stored in a cookie as a serialized array with this prototype:

```
[array]
(
    'session_id'    => random hash,
    'ip_address'    => 'string - user IP address',
    'user_agent'    => 'string - user agent data',
    'last_activity' => timestamp
)
```

: Sessions are only updated every five minutes by default to reduce processor load. If you repeatedly reload a page you'll notice that the "last activity" time only updates if five minutes or more has passed since the last time the cookie was written. This time is configurable by changing the `$config['sess_time_to_update']` line in your `system/config/config.php` file.

Retrieving Session Data

Any piece of information from the session array is available using the following function:

```
$this->session->userdata('item');
```

Where `item` is the array index corresponding to the item you wish to fetch. For example, to fetch the session ID you will do this:

```
$session_id = $this->session->userdata('session_id');
```

: The function returns NULL if the item you are trying to access does not exist.

Adding Custom Session Data

A useful aspect of the session array is that you can add your own data to it and it will be stored in the user's cookie. Why would you want to do this? Here's one example:

Let's say a particular user logs into your site. Once authenticated, you could add their username and email address to the session, making that data globally available to you without having to run a database query when you need it.

To add your data to the session array involves passing an array containing your new data to this function:

```
$this->session->set_userdata($array);
```

Where `$array` is an associative array containing your new data. Here's an example:

```
$newdata = array(
    'username' => 'johndoe',
    'email'    => 'johndoe@some-site.com',
    'logged_in' => TRUE
);

$this->session->set_userdata($newdata);
```

If you want to add userdata one value at a time, `set_userdata()` also supports this syntax.

```
$this->session->set_userdata('some_name', 'some_value');
```

If you want to verify that a userdata value exists, call `has_userdata()`.

```
$this->session->has_userdata('some_name');
```

Retrieving All Session Data

An array of all userdata can be retrieved as follows:

```
$this->session->all_userdata()
```

And returns an associative array like the following:

```
Array
(
    [session_id] => 4a5a5dca22728fb0a84364eeb405b601
    [ip_address] => 127.0.0.1
    [user_agent] => Mozilla/5.0 (Macintosh; U; Intel Mac OS X 10_6_7;
    [last_activity] => 1303142623
)
```

Removing Session Data

Just as `set_userdata()` can be used to add information into a session, `unset_userdata()` can be used to remove it, by passing the session key. For example, if you wanted to remove 'some_name' from your session information:

```
$this->session->unset_userdata('some_name');
```

This function can also be passed an associative array of items to unset.

```
$array_items = array('username' => '', 'email' => '');

$this->session->unset_userdata($array_items);
```

Flashdata

CodeIgniter supports “flashdata”, or session data that will only be available for the next server request, and are then automatically cleared. These can be very useful, and are typically used for informational or status messages (for example: “record 2 deleted”).

: Flash variables are prefaced with “flash_” so avoid this prefix in your own session names.

To add flashdata:

```
$this->session->set_flashdata('item', 'value');
```

You can also pass an array to `set_flashdata()`, in the same manner as `set_userdata()`.

To read a flashdata variable:

```
$this->session->flashdata('item');
```

An array of all flashdata can be retrieved as follows:

```
$this->session->all_flashdata();
```

If you find that you need to preserve a flashdata variable through an additional request, you can do so using the `keep_flashdata()` function. You can either pass a single item or an array of flashdata items to keep.

```
$this->session->keep_flashdata('item');  
$this->session->keep_flashdata(array('item1', 'item2', 'item3'));
```

Tempdata

CodeIgniter also supports “tempdata”, or session data with a specific expiration time. After the value expires, or the session expires or is deleted, the value is automatically removed.

To add tempdata:

```
$expire = 300; // Expire in 5 minutes  
  
$this->session->set_tempdata('item', 'value', $expire);
```

You can also pass an array to `set_tempdata()`:

```
$tempdata = array('newuser' => TRUE, 'message' => 'Thanks for joining!');  
  
$this->session->set_tempdata($tempdata, '', $expire);
```

: If the expiration is omitted or set to 0, the default expiration of 5 minutes will be used.

To read a tempdata variable:

```
$this->session->tempdata('item');
```

If you need to remove a tempdata value before it expires, use `unset_tempdata()`:

```
$this->session->unset_tempdata('item');
```

Destroying a Session

To clear the current session:

```
$this->session->sess_destroy();
```

: This function should be the last one called, and even flash variables will no longer be available. If you only want some items destroyed and not all, use `unset_userdata()`.

Session Preferences

You'll find the following Session related preferences in your *application/config/config.php* file:

Preference	Default	Options	Description
sess_driver	cookie	cookie/native/cookie	The initial session driver to load.
sess_valid_drivers	cookie, native	None	Additional valid drivers which may be loaded.
sess_cookie_name	sessionid	None	The name you want the session cookie saved as (data for Cookie driver or session ID for Native driver).
sess_expiration	7200	None	The number of seconds you would like the session to last. The default value is 2 hours (7200 seconds). If you would like a non-expiring session set the value to zero: 0
sess_expire_on_close	FALSE	TRUE/FALSE (boolean)	Whether to cause the session to expire automatically when the browser window is closed.
sess_encrypt_cookie	FALSE	TRUE/FALSE (boolean)	Whether to encrypt the session data (Cookie driver only).
sess_use_database	FALSE	TRUE/FALSE (boolean)	Whether to save the session data to a database. You must create the table before enabling this option (Cookie driver only).
sess_table_name	session	Any valid SQL table name	The name of the session database table (Cookie driver only).
sess_time_to_update	300	Time in seconds	This options controls how often the session class will regenerate itself and create a new session ID. Setting it to 0 will disable session ID regeneration.
sess_match_ip	FALSE	TRUE/FALSE (boolean)	Whether to match the user's IP address when reading the session data. Note that some ISPs dynamically changes the IP, so if you want a non-expiring session you will likely set this to FALSE.
sess_match_useragent	FALSE	TRUE/FALSE (boolean)	Whether to match the User Agent when reading the session data.

In addition to the values above, the cookie and native drivers apply the following configuration values shared by the *Input* and *Security* classes:

Preference	Default	Description
cookie_prefix	''	Set a cookie name prefix in order to avoid name collisions
cookie_domain	''	The domain for which the session is applicable
cookie_path	/	The path to which the session is applicable

Session Drivers

By default, the Cookie Driver is loaded when a session is initialized. However, any valid driver may be selected with the `$config['sess_driver']` line in your *config.php* file.

The session driver library comes with the cookie and native drivers installed, and Custom Drivers may also be installed by the user.

Typically, only one driver will be used at a time, but CodeIgniter does support loading multiple drivers. If a specific valid driver is called, it will be automatically loaded. Or, an additional driver may be explicitly loaded by calling `load_driver()`:

```
$this->session->load_driver('native');
```

The Session library keeps track of the most recently selected driver to call for driver methods. Normally, session class methods are called directly on the parent class, as illustrated above. However, any methods called through a specific driver will select that driver before invoking the parent method.

So, alternation between multiple drivers can be achieved by specifying which driver to use for each call:

```
$this->session->native->set_userdata('foo', 'bar');
```

```
$this->session->cookie->userdata('foo');
```

```
$this->session->native->unset_userdata('foo');
```

Notice in the previous example that the *native* userdata value 'foo' would be set to 'bar', which would NOT be returned by the call for the *cookie* userdata 'foo', nor would the *cookie* value be unset by the call to unset the *native* 'foo' value. The drivers maintain independent sets of values, regardless of key names.

A specific driver may also be explicitly selected for use by pursuant methods with the `select_driver()` call:

```
$this->session->select_driver('native');
```

```
$this->session->userdata('item');           // Uses the native driver
```

Cookie Driver

The Cookie driver stores session information for each user as serialized (and optionally encrypted) data in a cookie. It can also store the session data in a database table for added security, as this permits the session ID in the user's cookie to be matched against the stored session ID. By default only the cookie is saved. If you choose to use the database option you'll need to create the session table as indicated below.

If you have the encryption option enabled, the serialized array will be encrypted before being stored in the cookie, making the data highly secure and impervious to being read or altered by someone. More info regarding encryption can be *found here*, although the Session class will take care of initializing and encrypting the data automatically.

: Even if you are not using encrypted sessions, you must set an *encryption key* in your config file which is used to aid in preventing session data manipulation.

: Cookies can only hold 4KB of data, so be careful not to exceed the capacity. The encryption process in particular produces a longer data string than the original so keep careful track of how much data you are storing.

Saving Session Data to a Database While the session data array stored in the user's cookie contains a Session ID, unless you store session data in a database there is no way to validate it. For some applications that require little or no security, session ID validation may not be needed, but if your application requires security, validation is mandatory. Otherwise, an old session could be restored by a user modifying their cookies.

When session data is available in a database, every time a valid session is found in the user's cookie, a database query is performed to match it. If the session ID does not match, the session is destroyed. Session IDs can never be updated, they can only be generated when a new session is created.

In order to store sessions, you must first create a database table for this purpose. Here is the basic prototype (for MySQL) required by the session class:

```
CREATE TABLE IF NOT EXISTS `ci_sessions` (
    session_id varchar(40) DEFAULT '0' NOT NULL,
    ip_address varchar(45) DEFAULT '0' NOT NULL,
    user_agent varchar(120) NOT NULL,
    last_activity int(10) unsigned DEFAULT 0 NOT NULL,
    user_data text NOT NULL,
    PRIMARY KEY (session_id, ip_address, user_agent),
    KEY `last_activity_idx` (`last_activity`)
);
```

: By default the table is called `ci_sessions`, but you can name it anything you want as long as you update the `application/config/config.php` file so that it contains the name you have chosen. Once you have created your database table you can enable the database option in your `config.php` file as follows:

```
$config['sess_use_database'] = TRUE;
```

Once enabled, the Session class will store session data in the DB.

Make sure you've specified the table name in your config file as well:

```
$config['sess_table_name'] = 'ci_sessions';
```

: The Cookie driver has built-in garbage collection which clears out expired sessions so you do not need to write your own routine to do it.

Native Driver

The Native driver relies on native PHP sessions to store data in the `$_SESSION` superglobal array. All stored values continue to be available through `$_SESSION`, but flash- and temp- data items carry special prefixes.

Custom Drivers

You may also *create your own* custom session drivers. A session driver basically manages an array of name/value pairs with some sort of storage mechanism.

To make a new driver, extend `CI_Session_driver`. Overload the `initialize()` method and read or create session data. Then implement a save handler to write changed data to storage (`sess_save`), a destroy handler to remove deleted data (`sess_destroy`), a regenerate handler to make a new session ID (`sess_regenerate`), and an access handler to expose the data (`get_userdata`). Your initial class might look like:

```
class CI_Session_custom extends CI_Session_driver {
    protected function initialize()
    {
        // Read existing session data or create a new one
    }

    public function sess_save()
    {
        // Save current data to storage
    }
}
```

```
public function sess_destroy()
{
    // Destroy the current session and clean up storage
}

public function sess_regenerate()
{
    // Create new session ID
}

public function &get_userdata()
{
    // Return a reference to your userdata array
}
}
```

Notice that `get_userdata()` returns a reference so the parent library is accessing the same array the driver object is using. This saves memory and avoids synchronization issues during usage.

Put your driver in the `libraries/Session/drivers` folder anywhere in your package paths. This includes the application directory, the system directory, or any path you add with `$CI->load->add_package_path()`. Your driver must be named `CI_Session_<name>`, and your filename must be `Session_<name>.php`, preferably also capitalized, such as:

`CI_Session_foo` in `libraries/Session/drivers/Session_foo.php`

Then specify the driver by setting `'sess_driver'` in your `config.php` file or as a parameter when loading the `CI_Session` object:

```
$config['sess_driver'] = 'foo';
```

OR:

```
$CI->load->driver('session', array('sess_driver' => 'foo'));
```

The driver specified by `'sess_driver'` is automatically included as a valid driver. However, if you want to make a custom driver available as an option without making it the initially loaded driver, set `'sess_valid_drivers'` in your `config.php` file to an array including your driver name:

```
$config['sess_valid_drivers'] = array('sess_driver');
```

7.1.22 HTML Table Class

The Table Class provides functions that enable you to auto-generate HTML tables from arrays or database result sets.

Initializing the Class

Like most other classes in CodeIgniter, the Table class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('table');
```

Once loaded, the Table library object will be available using: `$this->table`

Examples

Here is an example showing how you can create a table from a multi-dimensional array. Note that the first array index will become the table heading (or you can set your own headings using the `set_heading()` function described in the function reference below).

```
$this->load->library('table');

$data = array(
    array('Name', 'Color', 'Size'),
    array('Fred', 'Blue', 'Small'),
    array('Mary', 'Red', 'Large'),
    array('John', 'Green', 'Medium')
);

echo $this->table->generate($data);
```

Here is an example of a table created from a database query result. The table class will automatically generate the headings based on the table names (or you can set your own headings using the `set_heading()` function described in the function reference below).

```
$this->load->library('table');

$query = $this->db->query("SELECT * FROM my_table");

echo $this->table->generate($query);
```

Here is an example showing how you might create a table using discrete parameters:

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');

$this->table->add_row('Fred', 'Blue', 'Small');
$this->table->add_row('Mary', 'Red', 'Large');
$this->table->add_row('John', 'Green', 'Medium');

echo $this->table->generate();
```

Here is the same example, except instead of individual parameters, arrays are used:

```
$this->load->library('table');

$this->table->set_heading(array('Name', 'Color', 'Size'));

$this->table->add_row(array('Fred', 'Blue', 'Small'));
$this->table->add_row(array('Mary', 'Red', 'Large'));
$this->table->add_row(array('John', 'Green', 'Medium'));

echo $this->table->generate();
```

Changing the Look of Your Table

The Table Class permits you to set a table template with which you can specify the design of your layout. Here is the template prototype:

```
$tmpl = array (
    'table_open'          => '<table border="0" cellpadding="4" cellspacing="0">',
```

```
'heading_row_start'    => '<tr>',
'heading_row_end'      => '</tr>',
'heading_cell_start'   => '<th>',
'heading_cell_end'     => '</th>',

'row_start'            => '<tr>',
'row_end'              => '</tr>',
'cell_start'           => '<td>',
'cell_end'             => '</td>',

'row_alt_start'        => '<tr>',
'row_alt_end'          => '</tr>',
'cell_alt_start'       => '<td>',
'cell_alt_end'         => '</td>',

'table_close'          => '</table>'

);

$this->table->set_template($tmpl);
```

: You'll notice there are two sets of "row" blocks in the template. These permit you to create alternating row colors or design elements that alternate with each iteration of the row data.

You are NOT required to submit a complete template. If you only need to change parts of the layout you can simply submit those elements. In this example, only the table opening tag is being changed:

```
$tmpl = array ( 'table_open'  => '<table border="1" cellpadding="2" cellspacing="1" class="mytable">'

$this->table->set_template($tmpl);
```

You can also set defaults for these in a config file.

Function Reference

`$this->table->generate()`

Returns a string containing the generated table. Accepts an optional parameter which can be an array or a database result object.

`$this->table->set_caption()`

Permits you to add a caption to the table.

```
$this->table->set_caption('Colors');
```

`$this->table->set_heading()`

Permits you to set the table heading. You can submit an array or discrete params:

```
$this->table->set_heading('Name', 'Color', 'Size');

$this->table->set_heading(array('Name', 'Color', 'Size'));
```

`$this->table->add_row()`

Permits you to add a row to your table. You can submit an array or discrete params:

```
$this->table->add_row('Blue', 'Red', 'Green');

$this->table->add_row(array('Blue', 'Red', 'Green'));
```

If you would like to set an individual cell's tag attributes, you can use an associative array for that cell. The associative key 'data' defines the cell's data. Any other key => val pairs are added as key='val' attributes to the tag:

```
$cell = array('data' => 'Blue', 'class' => 'highlight', 'colspan' => 2);
$this->table->add_row($cell, 'Red', 'Green');

// generates
// <td class='highlight' colspan='2'>Blue</td><td>Red</td><td>Green</td>
```

`$this->table->make_columns()`

This function takes a one-dimensional array as input and creates a multi-dimensional array with a depth equal to the number of columns desired. This allows a single array with many elements to be displayed in a table that has a fixed column count. Consider this example:

```
$list = array('one', 'two', 'three', 'four', 'five', 'six', 'seven', 'eight', 'nine', 'ten', 'eleven');

$new_list = $this->table->make_columns($list, 3);

$this->table->generate($new_list);

// Generates a table with this prototype

<table border="0" cellpadding="4" cellspacing="0">
<tr>
<td>one</td><td>two</td><td>three</td>
</tr><tr>
<td>four</td><td>five</td><td>six</td>
</tr><tr>
<td>seven</td><td>eight</td><td>nine</td>
</tr><tr>
<td>ten</td><td>eleven</td><td>twelve</td></tr>
</table>
```

`$this->table->set_template()`

Permits you to set your template. You can submit a full or partial template.

```
$tmpl = array ( 'table_open' => '<table border="1" cellpadding="2" cellspacing="1" class="mytable">');

$this->table->set_template($tmpl);
```

`$this->table->set_empty()`

Let's you set a default value for use in any table cells that are empty. You might, for example, set a non-breaking space:

```
$this->table->set_empty(" &nbsp;");
```

`$this->table->clear()`

Lets you clear the table heading and row data. If you need to show multiple tables with different data you should to call this function after each table has been generated to empty the previous table information. Example:

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');
$this->table->add_row('Fred', 'Blue', 'Small');
$this->table->add_row('Mary', 'Red', 'Large');
$this->table->add_row('John', 'Green', 'Medium');

echo $this->table->generate();

$this->table->clear();

$this->table->set_heading('Name', 'Day', 'Delivery');
$this->table->add_row('Fred', 'Wednesday', 'Express');
$this->table->add_row('Mary', 'Monday', 'Air');
$this->table->add_row('John', 'Saturday', 'Overnight');

echo $this->table->generate();
```

`$this->table->function`

Allows you to specify a native PHP function or a valid function array object to be applied to all cell data.

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');
$this->table->add_row('Fred', '<strong>Blue</strong>', 'Small');

$this->table->function = 'htmlspecialchars';
echo $this->table->generate();
```

In the above example, all cell data would be ran through PHP's `htmlspecialchars()` function, resulting in:

```
<td>Fred</td><td>&lt;strong&gt;Blue&lt;/strong&gt;</td><td>Small</td>
```

7.1.23 Trackback Class

The Trackback Class provides functions that enable you to send and receive Trackback data.

If you are not familiar with Trackbacks you'll find more information [here](#).

Initializing the Class

Like most other classes in CodeIgniter, the Trackback class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('trackback');
```

Once loaded, the Trackback library object will be available using: `$this->trackback`

Sending Trackbacks

A Trackback can be sent from any of your controller functions using code similar to this example:

```
$this->load->library('trackback');

$tb_data = array(
    'ping_url' => 'http://example.com/trackback/456',
    'url'      => 'http://www.my-example.com/blog/entry/123',
    'title'    => 'The Title of My Entry',
    'excerpt'  => 'The entry content.',
    'blog_name' => 'My Blog Name',
    'charset'  => 'utf-8'
);

if ( ! $this->trackback->send($tb_data) )
{
    echo $this->trackback->display_errors();
}
else
{
    echo 'Trackback was sent!';
}
```

Description of array data:

- **ping_url** - The URL of the site you are sending the Trackback to. You can send Trackbacks to multiple URLs by separating each URL with a comma.
- **url** - The URL to YOUR site where the weblog entry can be seen.
- **title** - The title of your weblog entry.
- **excerpt** - The content of your weblog entry. Note: the Trackback class will automatically send only the first 500 characters of your entry. It will also strip all HTML.
- **blog_name** - The name of your weblog.
- **charset** - The character encoding your weblog is written in. If omitted, UTF-8 will be used.

The Trackback sending function returns TRUE/FALSE (boolean) on success or failure. If it fails, you can retrieve the error message using:

```
$this->trackback->display_errors();
```

Receiving Trackbacks

Before you can receive Trackbacks you must create a weblog. If you don't have a blog yet there's no point in continuing.

Receiving Trackbacks is a little more complex than sending them, only because you will need a database table in which to store them, and you will need to validate the incoming trackback data. You are encouraged to implement a thorough validation process to guard against spam and duplicate data. You may also want to limit the number of Trackbacks you allow from a particular IP within a given span of time to further curtail spam. The process of receiving a Trackback is quite simple; the validation is what takes most of the effort.

Your Ping URL

In order to accept Trackbacks you must display a Trackback URL next to each one of your weblog entries. This will be the URL that people will use to send you Trackbacks (we will refer to this as your “Ping URL”).

Your Ping URL must point to a controller function where your Trackback receiving code is located, and the URL must contain the ID number for each particular entry, so that when the Trackback is received you’ll be able to associate it with a particular entry.

For example, if your controller class is called Trackback, and the receiving function is called receive, your Ping URLs will look something like this:

```
http://example.com/index.php/trackback/receive/entry_id
```

Where entry_id represents the individual ID number for each of your entries.

Creating a Trackback Table

Before you can receive Trackbacks you must create a table in which to store them. Here is a basic prototype for such a table:

```
CREATE TABLE trackbacks (
  tb_id int(10) unsigned NOT NULL auto_increment,
  entry_id int(10) unsigned NOT NULL default 0,
  url varchar(200) NOT NULL,
  title varchar(100) NOT NULL,
  excerpt text NOT NULL,
  blog_name varchar(100) NOT NULL,
  tb_date int(10) NOT NULL,
  ip_address varchar(45) NOT NULL,
  PRIMARY KEY `tb_id` (`tb_id`),
  KEY `entry_id` (`entry_id`)
);
```

The Trackback specification only requires four pieces of information to be sent in a Trackback (url, title, excerpt, blog_name), but to make the data more useful we’ve added a few more fields in the above table schema (date, IP address, etc.).

Processing a Trackback

Here is an example showing how you will receive and process a Trackback. The following code is intended for use within the controller function where you expect to receive Trackbacks.

```
$this->load->library('trackback');
$this->load->database();

if ($this->uri->segment(3) == FALSE)
{
    $this->trackback->send_error("Unable to determine the entry ID");
}

if ( ! $this->trackback->receive())
{
    $this->trackback->send_error("The Trackback did not contain valid data");
}

$data = array(
```

```

        'tb_id'      => '',
        'entry_id'   => $this->uri->segment(3),
        'url'        => $this->trackback->data('url'),
        'title'      => $this->trackback->data('title'),
        'excerpt'    => $this->trackback->data('excerpt'),
        'blog_name'  => $this->trackback->data('blog_name'),
        'tb_date'    => time(),
        'ip_address' => $this->input->ip_address()
    );

    $sql = $this->db->insert_string('trackbacks', $data);
    $this->db->query($sql);

    $this->trackback->send_success();

```

Notes:

The entry ID number is expected in the third segment of your URL. This is based on the URI example we gave earlier:

`http://example.com/index.php/trackback/receive/entry_id`

Notice the entry_id is in the third URI segment, which you can retrieve using:

```
$this->uri->segment(3);
```

In our Trackback receiving code above, if the third segment is missing, we will issue an error. Without a valid entry ID, there's no reason to continue.

The `$this->trackback->receive()` function is simply a validation function that looks at the incoming data and makes sure it contains the four pieces of data that are required (url, title, excerpt, blog_name). It returns TRUE on success and FALSE on failure. If it fails you will issue an error message.

The incoming Trackback data can be retrieved using this function:

```
$this->trackback->data('item')
```

Where item represents one of these four pieces of info: url, title, excerpt, or blog_name

If the Trackback data is successfully received, you will issue a success message using:

```
$this->trackback->send_success();
```

: The above code contains no data validation, which you are encouraged to add.

7.1.24 Typography Class

The Typography Class provides functions that help you format text.

Initializing the Class

Like most other classes in CodeIgniter, the Typography class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('typography');
```

Once loaded, the Typography library object will be available using: `$this->typography`

auto_typography()

Formats text so that it is semantically and typographically correct HTML. Takes a string as input and returns it with the following formatting:

- Surrounds paragraphs within `<p></p>` (looks for double line breaks to identify paragraphs).
- Single line breaks are converted to `
`, except those that appear within `<pre>` tags.
- Block level elements, like `<div>` tags, are not wrapped within paragraphs, but their contained text is if it contains paragraphs.
- Quotes are converted to correctly facing curly quote entities, except those that appear within tags.
- Apostrophes are converted to curly apostrophe entities.
- Double dashes (either like – this or like–this) are converted to em—dashes.
- Three consecutive periods either preceding or following a word are converted to ellipsis...
- Double spaces following sentences are converted to non-breaking spaces to mimic double spacing.

Usage example:

```
$string = $this->typography->auto_typography($string);
```

Parameters

There is one optional parameters that determines whether the parser should reduce more than two consecutive line breaks down to two. Use boolean TRUE or FALSE.

By default the parser does not reduce line breaks. In other words, if no parameters are submitted, it is the same as doing this:

```
$string = $this->typography->auto_typography($string, FALSE);
```

: Typographic formatting can be processor intensive, particularly if you have a lot of content being formatted. If you choose to use this function you may want to consider *caching* your pages.

format_characters()

This function is similar to the `auto_typography` function above, except that it only does character conversion:

- Quotes are converted to correctly facing curly quote entities, except those that appear within tags.
- Apostrophes are converted to curly apostrophe entities.
- Double dashes (either like – this or like–this) are converted to em—dashes.
- Three consecutive periods either preceding or following a word are converted to ellipsis...
- Double spaces following sentences are converted to non-breaking spaces to mimic double spacing.

Usage example:

```
$string = $this->typography->format_characters($string);
```

nl2br_except_pre()

Converts newlines to
 tags unless they appear within <pre> tags. This function is identical to the native PHP nl2br() function, except that it ignores <pre> tags.

Usage example:

```
$string = $this->typography->nl2br_except_pre($string);
```

protect_braced_quotes

When using the Typography library in conjunction with the Template Parser library it can often be desirable to protect single and double quotes within curly braces. To enable this, set the protect_braced_quotes class property to TRUE.

Usage example:

```
$this->load->library('typography');
$this->typography->protect_braced_quotes = TRUE;
```

7.1.25 Unit Testing Class

Unit testing is an approach to software development in which tests are written for each function in your application. If you are not familiar with the concept you might do a little googling on the subject.

CodeIgniter's Unit Test class is quite simple, consisting of an evaluation function and two result functions. It's not intended to be a full-blown test suite but rather a simple mechanism to evaluate your code to determine if it is producing the correct data type and result.

Initializing the Class

Like most other classes in CodeIgniter, the Unit Test class is initialized in your controller using the \$this->load->library function:

```
$this->load->library('unit_test');
```

Once loaded, the Unit Test object will be available using: \$this->unit

Running Tests

Running a test involves supplying a test and an expected result to the following function:

`$this->unit->run(test, expected result, 'test name', 'notes');`

Where test is the result of the code you wish to test, expected result is the data type you expect, test name is an optional name you can give your test, and notes are optional notes. Example:

```
$test = 1 + 1;

$expected_result = 2;

$test_name = 'Adds one plus one';

$this->unit->run($test, $expected_result, $test_name);
```

The expected result you supply can either be a literal match, or a data type match. Here's an example of a literal:

```
$this->unit->run('Foo', 'Foo');
```

Here is an example of a data type match:

```
$this->unit->run('Foo', 'is_string');
```

Notice the use of “is_string” in the second parameter? This tells the function to evaluate whether your test is producing a string as the result. Here is a list of allowed comparison types:

- is_object
- is_string
- is_bool
- is_true
- is_false
- is_int
- is_numeric
- is_float
- is_double
- is_array
- is_null

Generating Reports

You can either display results after each test, or you can run several tests and generate a report at the end. To show a report directly simply echo or return the run function:

```
echo $this->unit->run($test, $expected_result);
```

To run a full report of all tests, use this:

```
echo $this->unit->report();
```

The report will be formatted in an HTML table for viewing. If you prefer the raw data you can retrieve an array using:

```
echo $this->unit->result();
```

Strict Mode

By default the unit test class evaluates literal matches loosely. Consider this example:

```
$this->unit->run(1, TRUE);
```

The test is evaluating an integer, but the expected result is a boolean. PHP, however, due to its loose data-typing will evaluate the above code as TRUE using a normal equality test:

```
if (1 == TRUE) echo 'This evaluates as true';
```

If you prefer, you can put the unit test class in to strict mode, which will compare the data type as well as the value:

```
if (1 === TRUE) echo 'This evaluates as FALSE';
```

To enable strict mode use this:

```
$this->unit->use_strict(TRUE);
```

Enabling/Disabling Unit Testing

If you would like to leave some testing in place in your scripts, but not have it run unless you need it, you can disable unit testing using:

```
$this->unit->active(FALSE)
```

Unit Test Display

When your unit test results display, the following items show by default:

- Test Name (test_name)
- Test Datatype (test_datatype)
- Expected Datatype (res_datatype)
- Result (result)
- File Name (file)
- Line Number (line)
- Any notes you entered for the test (notes)

You can customize which of these items get displayed by using `$this->unit->set_test_items()`. For example, if you only wanted the test name and the result displayed:

Customizing displayed tests

```
$this->unit->set_test_items(array('test_name', 'result'));
```

Creating a Template

If you would like your test results formatted differently then the default you can set your own template. Here is an example of a simple template. Note the required pseudo-variables:

```
$str = '
<table border="0" cellpadding="4" cellspacing="1">
    {rows}
    <tr>
        <td>{item}</td>
        <td>{result}</td>
    </tr>
    {/rows}
</table>';
```

```
$this->unit->set_template($str);
```

: Your template must be declared **before** running the unit test process.

7.1.26 URI Class

The URI Class provides functions that help you retrieve information from your URI strings. If you use URI routing, you can also retrieve information about the re-routed segments.

: This class is initialized automatically by the system so there is no need to do it manually.

`$this->uri->segment(n)`

Permits you to retrieve a specific segment. Where *n* is the segment number you wish to retrieve. Segments are numbered from left to right. For example, if your full URL is this:

```
http://example.com/index.php/news/local/metro/crime_is_up
```

The segment numbers would be this:

1. news
2. local
3. metro
4. crime_is_up

By default the function returns NULL if the segment does not exist. There is an optional second parameter that permits you to set your own default value if the segment is missing. For example, this would tell the function to return the number zero in the event of failure:

```
$product_id = $this->uri->segment(3, 0);
```

It helps avoid having to write code like this:

```
if ($this->uri->segment(3) === FALSE)
{
    $product_id = 0;
}
else
{
    $product_id = $this->uri->segment(3);
}
```

`$this->uri->rsegment(n)`

This function is identical to the previous one, except that it lets you retrieve a specific segment from your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->slash_segment(n)`

This function is almost identical to `$this->uri->segment()`, except it adds a trailing and/or leading slash based on the second parameter. If the parameter is not used, a trailing slash added. Examples:

```
$this->uri->slash_segment(3);
$this->uri->slash_segment(3, 'leading');
$this->uri->slash_segment(3, 'both');
```

Returns:

1. segment/
2. /segment
3. /segment/

`$this->uri->slash_rsegment(n)`

This function is identical to the previous one, except that it lets you add slashes a specific segment from your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->uri_to_assoc(n)`

This function lets you turn URI segments into an associative array of key/value pairs. Consider this URI:

```
index.php/user/search/name/joe/location/UK/gender/male
```

Using this function you can turn the URI into an associative array with this prototype:

```
[array]
(
    'name' => 'joe'
    'location' => 'UK'
    'gender' => 'male'
)
```

The first parameter of the function lets you set an offset. By default it is set to 3 since your URI will normally contain a controller/function in the first and second segments. Example:

```
$array = $this->uri->uri_to_assoc(3);

echo $array['name'];
```

The second parameter lets you set default key names, so that the array returned by the function will always contain expected indexes, even if missing from the URI. Example:

```
$default = array('name', 'gender', 'location', 'type', 'sort');

$array = $this->uri->uri_to_assoc(3, $default);
```

If the URI does not contain a value in your default, an array index will be set to that name, with a value of FALSE.

Lastly, if a corresponding value is not found for a given key (if there is an odd number of URI segments) the value will be set to FALSE (boolean).

`$this->uri->ruri_to_assoc(n)`

This function is identical to the previous one, except that it creates an associative array using the re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->assoc_to_uri()`

Takes an associative array as input and generates a URI string from it. The array keys will be included in the string.
Example:

```
$array = array('product' => 'shoes', 'size' => 'large', 'color' => 'red');  
  
$str = $this->uri->assoc_to_uri($array);  
  
// Produces: product/shoes/size/large/color/red
```

`$this->uri->uri_string()`

Returns a string with the complete URI. For example, if this is your full URL:

```
http://example.com/index.php/news/local/345
```

The function would return this:

```
news/local/345
```

`$this->uri->ruri_string()`

This function is identical to the previous one, except that it returns the re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->total_segments()`

Returns the total number of segments.

`$this->uri->total_rsegments()`

This function is identical to the previous one, except that it returns the total number of segments in your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->segment_array()`

Returns an array containing the URI segments. For example:

```
$segs = $this->uri->segment_array();  
  
foreach ($segs as $segment)  
{  
    echo $segment;  
    echo '<br />';  
}
```

`$this->uri->rsegment_array()`

This function is identical to the previous one, except that it returns the array of segments in your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

7.1.27 User Agent Class

The User Agent Class provides functions that help identify information about the browser, mobile device, or robot visiting your site. In addition you can get referrer information as well as language and supported character-set information.

Initializing the Class

Like most other classes in CodeIgniter, the User Agent class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('user_agent');
```

Once loaded, the object will be available using: `$this->agent`

User Agent Definitions

The user agent name definitions are located in a config file located at: `application/config/user_agents.php`. You may add items to the various user agent arrays if needed.

Example

When the User Agent class is initialized it will attempt to determine whether the user agent browsing your site is a web browser, a mobile device, or a robot. It will also gather the platform information if it is available.

```
$this->load->library('user_agent');

if ($this->agent->is_browser())
{
    $agent = $this->agent->browser().' '.$this->agent->version();
}
elseif ($this->agent->is_robot())
{
    $agent = $this->agent->robot();
}
elseif ($this->agent->is_mobile())
{
    $agent = $this->agent->mobile();
}
else
{
    $agent = 'Unidentified User Agent';
}

echo $agent;

echo $this->agent->platform(); // Platform info (Windows, Linux, Mac, etc.)
```

Function Reference

`$this->agent->is_browser()`

Returns TRUE/FALSE (boolean) if the user agent is a known web browser.

```
if ($this->agent->is_browser('Safari'))
{
    echo 'You are using Safari.';
}
elseif ($this->agent->is_browser())
{
    echo 'You are using a browser.';
}
```

: The string “Safari” in this example is an array key in the list of browser definitions. You can find this list in `application/config/user_agents.php` if you want to add new browsers or change the stings.

`$this->agent->is_mobile()`

Returns TRUE/FALSE (boolean) if the user agent is a known mobile device.

```
if ($this->agent->is_mobile('iphone'))
{
    $this->load->view('iphone/home');
}
elseif ($this->agent->is_mobile())
{
    $this->load->view('mobile/home');
}
else
{
    $this->load->view('web/home');
}
```

`$this->agent->is_robot()`

Returns TRUE/FALSE (boolean) if the user agent is a known robot.

: The user agent library only contains the most common robot definitions. It is not a complete list of bots. There are hundreds of them so searching for each one would not be very efficient. If you find that some bots that commonly visit your site are missing from the list you can add them to your `application/config/user_agents.php` file.

`$this->agent->is_referral()`

Returns TRUE/FALSE (boolean) if the user agent was referred from another site.

`$this->agent->browser()`

Returns a string containing the name of the web browser viewing your site.

`$this->agent->version()`

Returns a string containing the version number of the web browser viewing your site.

`$this->agent->mobile()`

Returns a string containing the name of the mobile device viewing your site.

`$this->agent->robot()`

Returns a string containing the name of the robot viewing your site.

`$this->agent->platform()`

Returns a string containing the platform viewing your site (Linux, Windows, OS X, etc.).

`$this->agent->referrer()`

The referrer, if the user agent was referred from another site. Typically you'll test for this as follows:

```
if ($this->agent->is_referral())
{
    echo $this->agent->referrer();
}
```

`$this->agent->agent_string()`

Returns a string containing the full user agent string. Typically it will be something like this:

Mozilla/5.0 (Macintosh; U; Intel Mac OS X; en-US; rv:1.8.0.4) Gecko/20060613 Camino/1.0.2

`$this->agent->accept_lang()`

Lets you determine if the user agent accepts a particular language. Example:

```
if ($this->agent->accept_lang('en'))
{
    echo 'You accept English!';
}
```

: This function is not typically very reliable since some browsers do not provide language info, and even among those that do, it is not always accurate.

`$this->agent->accept_charset()`

Lets you determine if the user agent accepts a particular character set. Example:

```
if ($this->agent->accept_charset('utf-8'))
{
    echo 'You browser supports UTF-8!';
}
```

: This function is not typically very reliable since some browsers do not provide character-set info, and even among those that do, it is not always accurate.

7.1.28 XML-RPC and XML-RPC Server Classes

CodeIgniter's XML-RPC classes permit you to send requests to another server, or set up your own XML-RPC server to receive requests.

What is XML-RPC?

Quite simply it is a way for two computers to communicate over the internet using XML. One computer, which we will call the client, sends an XML-RPC **request** to another computer, which we will call the server. Once the server receives and processes the request it will send back a **response** to the client.

For example, using the MetaWeblog API, an XML-RPC Client (usually a desktop publishing tool) will send a request to an XML-RPC Server running on your site. This request might be a new weblog entry being sent for publication, or it could be a request for an existing entry for editing. When the XML-RPC Server receives this request it will examine it to determine which class/method should be called to process the request. Once processed, the server will then send back a response message.

For detailed specifications, you can visit the [XML-RPC](#) site.

Initializing the Class

Like most other classes in CodeIgniter, the XML-RPC and XML-RPCS classes are initialized in your controller using the `$this->load->library` function:

To load the XML-RPC class you will use:

```
$this->load->library('xmlrpc');
```

Once loaded, the xml-rpc library object will be available using: `$this->xmlrpc`

To load the XML-RPC Server class you will use:

```
$this->load->library('xmlrpc');  
$this->load->library('xmlrpcs');
```

Once loaded, the xml-rpcs library object will be available using: `$this->xmlrpcs`

: When using the XML-RPC Server class you must load BOTH the XML-RPC class and the XML-RPC Server class.

Sending XML-RPC Requests

To send a request to an XML-RPC server you must specify the following information:

- The URL of the server
- The method on the server you wish to call
- The *request* data (explained below).

Here is a basic example that sends a simple Weblogs.com ping to the [Ping-o-Matic](#)

```
$this->load->library('xmlrpc');  
  
$this->xmlrpc->server('http://rpc.pingomatic.com/', 80);  
$this->xmlrpc->method('weblogUpdates.ping');  
  
$request = array('My Photoblog', 'http://www.my-site.com/photoblog/');
```

```

$this->xmlrpc->request($request);

if ( ! $this->xmlrpc->send_request() )
{
    echo $this->xmlrpc->display_error();
}

```

Explanation The above code initializes the XML-RPC class, sets the server URL and method to be called (we-blogUpdates.ping). The request (in this case, the title and URL of your site) is placed into an array for transportation, and compiled using the request() function. Lastly, the full request is sent. If the send_request() method returns false we will display the error message sent back from the XML-RPC Server.

Anatomy of a Request

An XML-RPC request is simply the data you are sending to the XML-RPC server. Each piece of data in a request is referred to as a request parameter. The above example has two parameters: The URL and title of your site. When the XML-RPC server receives your request, it will look for parameters it requires.

Request parameters must be placed into an array for transportation, and each parameter can be one of seven data types (strings, numbers, dates, etc.). If your parameters are something other than strings you will have to include the data type in the request array.

Here is an example of a simple array with three parameters:

```

$request = array('John', 'Doe', 'www.some-site.com');
$this->xmlrpc->request($request);

```

If you use data types other than strings, or if you have several different data types, you will place each parameter into its own array, with the data type in the second position:

```

$request = array (
    array('John', 'string'),
    array('Doe', 'string'),
    array(FALSE, 'boolean'),
    array(12345, 'int')
);
$this->xmlrpc->request($request);

```

The Data Types section below has a full list of data types. Creating an XML-RPC Server
=====

An XML-RPC Server acts as a traffic cop of sorts, waiting for incoming requests and redirecting them to the appropriate functions for processing.

To create your own XML-RPC server involves initializing the XML-RPC Server class in your controller where you expect the incoming request to appear, then setting up an array with mapping instructions so that incoming requests can be sent to the appropriate class and method for processing.

Here is an example to illustrate:

```

$this->load->library('xmlrpc');
$this->load->library('xmlrpcs');

$config['functions']['new_post'] = array('function' => 'My_blog.new_entry'),
$config['functions']['update_post'] = array('function' => 'My_blog.update_entry');
$config['object'] = $this;

```

```
$this->xmlrpcs->initialize($config);  
$this->xmlrpcs->serve();
```

The above example contains an array specifying two method requests that the Server allows. The allowed methods are on the left side of the array. When either of those are received, they will be mapped to the class and method on the right.

The ‘object’ key is a special key that you pass an instantiated class object with, which is necessary when the method you are mapping to is not part of the CodeIgniter super object.

In other words, if an XML-RPC Client sends a request for the new_post method, your server will load the My_blog class and call the new_entry function. If the request is for the update_post method, your server will load the My_blog class and call the update_entry function.

The function names in the above example are arbitrary. You’ll decide what they should be called on your server, or if you are using standardized APIs, like the Blogger or MetaWeblog API, you’ll use their function names.

There are two additional configuration keys you may make use of when initializing the server class: debug can be set to TRUE in order to enable debugging, and xss_clean may be set to FALSE to prevent sending data through the Security library’s xss_clean function.

Processing Server Requests

When the XML-RPC Server receives a request and loads the class/method for processing, it will pass an object to that method containing the data sent by the client.

Using the above example, if the new_post method is requested, the server will expect a class to exist with this prototype:

```
class My_blog extends CI_Controller {  
  
    public function new_post($request)  
    {  
  
    }  
  
}
```

The \$request variable is an object compiled by the Server, which contains the data sent by the XML-RPC Client. Using this object you will have access to the *request parameters* enabling you to process the request. When you are done you will send a Response back to the Client.

Below is a real-world example, using the Blogger API. One of the methods in the Blogger API is getUserInfo(). Using this method, an XML-RPC Client can send the Server a username and password, in return the Server sends back information about that particular user (nickname, user ID, email address, etc.). Here is how the processing function might look:

```
class My_blog extends CI_Controller {  
  
    function getUserInfo($request)  
    {  
        $username = 'smitty';  
        $password = 'secretsmittypass';  
  
        $this->load->library('xmlrpc');  
  
        $parameters = $request->output_parameters();  
  
        if ($parameters['1'] != $username AND $parameters['2'] != $password)
```

```

    {
        return $this->xmlrpc->send_error_message('100', 'Invalid Access');
    }

    $response = array(array('nickname' => array('Smitty','string'),
                           'userid'   => array('99','string'),
                           'url'      => array('http://yoursite.com','string'),
                           'email'    => array('jsmith@yoursite.com','string'),
                           'lastname' => array('Smith','string'),
                           'firstname' => array('John','string')
                           ),
                      'struct');

    return $this->xmlrpc->send_response($response);
}
}

```

Notes: The `output_parameters()` function retrieves an indexed array corresponding to the request parameters sent by the client. In the above example, the output parameters will be the username and password.

If the username and password sent by the client were not valid, and error message is returned using `send_error_message()`.

If the operation was successful, the client will be sent back a response array containing the user's info.

Formatting a Response

Similar to *Requests*, *Responses* must be formatted as an array. However, unlike requests, a response is an array **that contains a single item**. This item can be an array with several additional arrays, but there can be only one primary array index. In other words, the basic prototype is this:

```
$response = array('Response data', 'array');
```

Responses, however, usually contain multiple pieces of information. In order to accomplish this we must put the response into its own array so that the primary array continues to contain a single piece of data. Here's an example showing how this might be accomplished:

```

$response = array (
    array(
        'first_name' => array('John', 'string'),
        'last_name'  => array('Doe', 'string'),
        'member_id'  => array(123435, 'int'),
        'todo_list'  => array(array('clean house', 'call mom', 'water plants'), 'array')
    ),
    'struct'
);

```

Notice that the above array is formatted as a struct. This is the most common data type for responses.

As with Requests, a response can be one of the seven data types listed in the Data Types section.

Sending an Error Response

If you need to send the client an error response you will use the following:

```
return $this->xmlrpc->send_error_message('123', 'Requested data not available');
```

The first parameter is the error number while the second parameter is the error message.

Creating Your Own Client and Server

To help you understand everything we've covered thus far, let's create a couple controllers that act as XML-RPC Client and Server. You'll use the Client to send a request to the Server and receive a response.

The Client Using a text editor, create a controller called `Xmlrpc_client.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Xmlrpc_client extends CI_Controller {

    public function index()
    {
        $this->load->helper('url');
        $server_url = site_url('xmlrpc_server');

        $this->load->library('xmlrpc');

        $this->xmlrpc->server($server_url, 80);
        $this->xmlrpc->method('Greetings');

        $request = array('How is it going?');
        $this->xmlrpc->request($request);

        if ( ! $this->xmlrpc->send_request() )
        {
            echo $this->xmlrpc->display_error();
        }
        else
        {
            echo '<pre>';
            print_r($this->xmlrpc->display_response());
            echo '</pre>';
        }
    }
}

?>
```

: In the above code we are using a “url helper”. You can find more information in the *Helpers Functions* page.

The Server Using a text editor, create a controller called `Xmlrpc_server.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Xmlrpc_server extends CI_Controller {

    public function index()
    {
```

```

        $this->load->library('xmlrpc');
        $this->load->library('xmlrpcs');

        $config['functions']['Greetings'] = array('function' => 'Xmlrpc_server.process');

        $this->xmlrpcs->initialize($config);
        $this->xmlrpcs->serve();
    }

    public function process($request)
    {
        $parameters = $request->output_parameters();

        $response = array(
            array(
                'you_said' => $parameters[0],
                'i_respond' => 'Not bad at all.'
            ),
            'struct'
        );

        return $this->xmlrpc->send_response($response);
    }
}
?>

```

Try it! Now visit the your site using a URL similar to this:

`example.com/index.php/xmlrpc_client/`

You should now see the message you sent to the server, and its response back to you.

The client you created sends a message (“How’s is going?”) to the server, along with a request for the “Greetings” method. The Server receives the request and maps it to the “process” function, where a response is sent back.

Using Associative Arrays In a Request Parameter

If you wish to use an associative array in your method parameters you will need to use a struct datatype:

```

$request = array(
    array(
        // Param 0
        array(
            'name'=>'John'
        ),
        'struct'
    ),
    array(
        // Param 1
        array(
            'size'=>'large',
            'shape'=>'round'
        ),
        'struct'
    )
)

```

```
        );  
$this->xmlrpc->request($request);
```

You can retrieve the associative array when processing the request in the Server.

```
$parameters = $request->output_parameters();  
$name = $parameters[0]['name'];  
$size = $parameters[1]['size'];  
$shape = $parameters[1]['shape'];
```

XML-RPC Function Reference

`$this->xmlrpc->server()`

Sets the URL and port number of the server to which a request is to be sent:

```
$this->xmlrpc->server('http://www.sometimes.com/pings.php', 80);
```

`$this->xmlrpc->timeout()`

Set a time out period (in seconds) after which the request will be canceled:

```
$this->xmlrpc->timeout(6);
```

`$this->xmlrpc->method()`

Sets the method that will be requested from the XML-RPC server:

```
$this->xmlrpc->method('method');
```

Where method is the name of the method.

`$this->xmlrpc->request()`

Takes an array of data and builds request to be sent to XML-RPC server:

```
$request = array(array('My Photoblog', 'string'), 'http://www.yoursite.com/photoblog/');  
$this->xmlrpc->request($request);
```

`$this->xmlrpc->send_request()`

The request sending function. Returns boolean TRUE or FALSE based on success for failure, enabling it to be used conditionally.

`$this->xmlrpc->set_debug(TRUE);`

Enables debugging, which will display a variety of information and error data helpful during development.

`$this->xmlrpc->display_error()`

Returns an error message as a string if your request failed for some reason.

```
echo $this->xmlrpc->display_error();
```

`$this->xmlrpc->display_response()`

Returns the response from the remote server once request is received. The response will typically be an associative array.

```
$this->xmlrpc->display_response();
```

`$this->xmlrpc->send_error_message()`

This function lets you send an error message from your server to the client. First parameter is the error number while the second parameter is the error message.

```
return $this->xmlrpc->send_error_message('123', 'Requested data not available');
```

`$this->xmlrpc->send_response()`

Lets you send the response from your server to the client. An array of valid data values must be sent with this method.

```
$response = array(
    array(
        'flerror' => array(FALSE, 'boolean'),
        'message' => "Thanks for the ping!"
    )
    'struct');
return $this->xmlrpc->send_response($response);
```

Data Types

According to the [XML-RPC spec](#) there are seven types of values that you can send via XML-RPC:

- *int* or *i4*
- *boolean*
- *string*
- *double*
- *dateTime.iso8601*
- *base64*
- *struct* (contains array of values)
- *array* (contains array of values)

7.1.29 Zip Encoding Class

CodeIgniter's Zip Encoding Class classes permit you to create Zip archives. Archives can be downloaded to your desktop or saved to a directory.

Initializing the Class

Like most other classes in CodeIgniter, the Zip class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('zip');
```

Once loaded, the Zip library object will be available using: `$this->zip`

Usage Example

This example demonstrates how to compress a file, save it to a folder on your server, and download it to your desktop.

```
$name = 'mydata1.txt';
$data = 'A Data String!';

$this->zip->add_data($name, $data);

// Write the zip file to a folder on your server. Name it "my_backup.zip"
$this->zip->archive('/path/to/directory/my_backup.zip');

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

Function Reference

`$this->zip->add_data()`

Permits you to add data to the Zip archive. The first parameter must contain the name you would like given to the file, the second parameter must contain the file data as a string:

```
$name = 'my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);
```

You are allowed multiple calls to this function in order to add several files to your archive. Example:

```
$name = 'mydata1.txt';
$data = 'A Data String!';
$this->zip->add_data($name, $data);

$name = 'mydata2.txt';
$data = 'Another Data String!';
$this->zip->add_data($name, $data);
```

Or you can pass multiple files using an array:

```
$data = array(
    'mydata1.txt' => 'A Data String!',
    'mydata2.txt' => 'Another Data String!'
);

$this->zip->add_data($data);

$this->zip->download('my_backup.zip');
```

If you would like your compressed data organized into sub-folders, include the path as part of the filename:

```
$name = 'personal/my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);
```

The above example will place my_bio.txt inside a folder called personal.

\$this->zip->add_dir()

Permits you to add a directory. Usually this function is unnecessary since you can place your data into folders when using `$this->zip->add_data()`, but if you would like to create an empty folder you can do so. Example:

```
$this->zip->add_dir('myfolder'); // Creates a folder called "myfolder"
```

\$this->zip->read_file()

Permits you to compress a file that already exists somewhere on your server. Supply a file path and the zip class will read it and add it to the archive:

```
$path = '/path/to/photo.jpg';

$this->zip->read_file($path);

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

If you would like the Zip archive to maintain the directory structure of the file in it, pass TRUE (boolean) in the second parameter. Example:

```
$path = '/path/to/photo.jpg';

$this->zip->read_file($path, TRUE);

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

In the above example, photo.jpg will be placed inside two folders: path/to/

\$this->zip->read_dir()

Permits you to compress a folder (and its contents) that already exists somewhere on your server. Supply a file path to the directory and the zip class will recursively read it and recreate it as a Zip archive. All files contained within the supplied path will be encoded, as will any sub-folders contained within it. Example:

```
$path = '/path/to/your/directory/';

$this->zip->read_dir($path);

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

By default the Zip archive will place all directories listed in the first parameter inside the zip. If you want the tree preceding the target folder to be ignored you can pass FALSE (boolean) in the second parameter. Example:

```
$path = '/path/to/your/directory/';

$this->zip->read_dir($path, FALSE);
```

This will create a ZIP with the folder “directory” inside, then all sub-folders stored correctly inside that, but will not include the folders /path/to/your.

\$this->zip->archive()

Writes the Zip-encoded file to a directory on your server. Submit a valid server path ending in the file name. Make sure the directory is writable (666 or 777 is usually OK). Example:

```
$this->zip->archive('/path/to/folder/myarchive.zip'); // Creates a file named myarchive.zip
```

\$this->zip->download()

Causes the Zip file to be downloaded from your server. The function must be passed the name you would like the zip file called. Example:

```
$this->zip->download('latest_stuff.zip'); // File will be named "latest_stuff.zip"
```

: Do not display any data in the controller in which you call this function since it sends various server headers that cause the download to happen and the file to be treated as binary.

\$this->zip->get_zip()

Returns the Zip-compressed file data. Generally you will not need this function unless you want to do something unique with the data. Example:

```
$name = 'my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);

$zip_file = $this->zip->get_zip();
```

\$this->zip->clear_data()

The Zip class caches your zip data so that it doesn't need to recompile the Zip archive for each function you use above. If, however, you need to create multiple Zips, each with different data, you can clear the cache between calls. Example:

```
$name = 'my_bio.txt';  
$data = 'I was born in an elevator...';  
  
$this->zip->add_data($name, $data);  
$zip_file = $this->zip->get_zip();  
  
$this->zip->clear_data();  
  
$name = 'photo.jpg';  
$this->zip->read_file("/path/to/photo.jpg"); // Read the file's contents  
  
$this->zip->download('myphotos.zip');
```

9.1 Helpers

9.1.1 Array Helper

The Array Helper file contains functions that assist in working with arrays.

Page Contents

- Array Helper
 - Loading this Helper
 - `element()`
 - `elements()`
 - `random_element()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('array');
```

The following functions are available:

`element()`

`element` (*\$item*, *\$array*, *\$default = NULL*)

- **`$item`** (*string*) – Item to fetch from the array
- **`$array`** (*array*) – Input array
- **`$default`** (*bool*) – What to return if the array isn't valid

NULL on failure or the array item.

Lets you fetch an item from an array. The function tests whether the array index is set and whether it has a value. If a value exists it is returned. If a value does not exist it returns NULL, or whatever you've specified as the default value via the third parameter.

Example:

```
$array = array(
    'color' => 'red',
    'shape' => 'round',
    'size'  => ''
);

echo element('color', $array); // returns "red"
echo element('size', $array, 'foobar'); // returns "foobar"
```

elements()

elements (*\$items*, *\$array*, *\$default = NULL*)

- **\$item** (*string*) – Item to fetch from the array
- **\$array** (*array*) – Input array
- **\$default** (*bool*) – What to return if the array isn't valid

NULL on failure or the array item.

Lets you fetch a number of items from an array. The function tests whether each of the array indices is set. If an index does not exist it is set to NULL, or whatever you've specified as the default value via the third parameter.

Example:

```
$array = array(
    'color' => 'red',
    'shape' => 'round',
    'radius' => '10',
    'diameter' => '20'
);

$my_shape = elements(array('color', 'shape', 'height'), $array);
```

The above will return the following array:

```
array(
    'color' => 'red',
    'shape' => 'round',
    'height' => NULL
);
```

You can set the third parameter to any default value you like.

```
$my_shape = elements(array('color', 'shape', 'height'), $array, 'foobar');
```

The above will return the following array:

```
array(
    'color'      => 'red',
    'shape'      => 'round',
    'height'     => 'foobar'
);
```

This is useful when sending the `$_POST` array to one of your Models. This prevents users from sending additional POST data to be entered into your tables.

```
$this->load->model('post_model');
$this->post_model->update(
    elements(array('id', 'title', 'content'), $_POST)
);
```

This ensures that only the id, title and content fields are sent to be updated.

random_element()

random_element (\$array)

- **\$array** (*array*) – Input array
- string (a random element from the array)

Takes an array as input and returns a random element from it.

Usage example:

```
$quotes = array(
    "I find that the harder I work, the more luck I seem to have. - Thomas Jefferson",
    "Don't stay in bed, unless you can make money in bed. - George Burns",
    "We didn't lose the game; we just ran out of time. - Vince Lombardi",
    "If everything seems under control, you're not going fast enough. - Mario Andretti",
    "Reality is merely an illusion, albeit a very persistent one. - Albert Einstein",
    "Chance favors the prepared mind - Louis Pasteur"
);

echo random_element($quotes);
```

9.1.2 CAPTCHA Helper

The CAPTCHA Helper file contains functions that assist in creating CAPTCHA images.

Page Contents

- CAPTCHA Helper
 - Loading this Helper
 - create_captcha()
 - * Using the CAPTCHA helper
 - * Adding a Database

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('captcha');
```

The following functions are available:

create_captcha()

```
function create_captcha($data = '', $img_path = '', $img_url = '', $font_path = '')
```

- **\$data** (*array*) – Array of data for the CAPTCHA
- **\$img_path** (*string*) – Path to create the image in
- **\$img_url** (*string*) – URL to the CAPTCHA image folder
- **\$font_path** (*string*) – Server path to font

array

Takes an array of information to generate the CAPTCHA as input and creates the image to your specifications, returning an array of associative data about the image.

```
array(  
    'word'      => CAPTCHA WORD,  
    'time'      => TIMESTAMP (in microtime),  
    'image'     => IMAGE TAG,  
    'filename'  => IMAGE FILE NAME  
)
```

The **image** is the actual image tag:

```

```

The **time** is the micro timestamp used as the image name without the file extension. It will be a number like this: 1139612155.3422

The **word** is the word that appears in the captcha image, which if not supplied to the function, will be a random string.

Using the CAPTCHA helper

Once loaded you can generate a captcha like this:

```
$vals = array(  
    'word'      => 'Random word',  
    'img_path'  => './captcha/',  
    'img_url'   => 'http://example.com/captcha/',  
    'font_path' => './path/to/fonts/texb.ttf',  
    'img_width' => '150',  
    'img_height' => 30,  
    'expiration' => 7200,  
    'word_length' => 8,  
    'pool'      => '0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ',  
  
    // White background and border, black text and red grid  
    'colors'    => array(  
        'background' => array(255, 255, 255),  
        'border'     => array(255, 255, 255),  
        'text'       => array(0, 0, 0),  
        'grid'       => array(255, 40, 40)  
    )  
);  
  
$cap = create_captcha($vals);  
echo $cap['image'];
```

- The captcha function requires the GD image library.
- Only the **img_path** and **img_url** are required.
- If a **word** is not supplied, the function will generate a random ASCII string. You might put together your own word library that you can draw randomly from.
- If you do not specify a path to a TRUE TYPE font, the native ugly GD font will be used.
- The “captcha” folder must be writable (666, or 777)
- The **expiration** (in seconds) signifies how long an image will remain in the captcha folder before it will be deleted. The default is two hours.
- **word_length** defaults to 8, **pool** defaults to ‘0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOSTQRSTUVWXYZ’
- If any of the **colors** values is missing, it will be replaced by the default.

Adding a Database

In order for the captcha function to prevent someone from submitting, you will need to add the information returned from `create_captcha()` to your database. Then, when the data from the form is submitted by the user you will need to verify that the data exists in the database and has not expired.

Here is a table prototype:

```
CREATE TABLE captcha (
    captcha_id bigint(13) unsigned NOT NULL auto_increment,
    captcha_time int(10) unsigned NOT NULL,
    ip_address varchar(45) NOT NULL,
    word varchar(20) NOT NULL,
    PRIMARY KEY `captcha_id` (`captcha_id`),
    KEY `word` (`word`)
);
```

Here is an example of usage with a database. On the page where the CAPTCHA will be shown you’ll have something like this:

```
$this->load->helper('captcha');
$vals = array(
    'img_path'      => './captcha/',
    'img_url'       => 'http://example.com/captcha/'
);

$cap = create_captcha($vals);
$data = array(
    'captcha_time'  => $cap['time'],
    'ip_address'    => $this->input->ip_address(),
    'word'          => $cap['word']
);

$query = $this->db->insert_string('captcha', $data);
$this->db->query($query);

echo 'Submit the word you see below:';
echo $cap['image'];
echo '<input type="text" name="captcha" value="" />';
```

Then, on the page that accepts the submission you’ll have something like this:

```
// First, delete old captchas
$expiration = time() - 7200; // Two hour limit
$this->db->where('captcha_time < ', $expiration)
    ->delete('captcha');

// Then see if a captcha exists:
$sql = 'SELECT COUNT(*) AS count FROM captcha WHERE word = ? AND ip_address = ? AND captcha_time > ?';
$binds = array($_POST['captcha'], $this->input->ip_address(), $expiration);
$query = $this->db->query($sql, $binds);
$row = $query->row();

if ($row->count == 0)
{
    echo 'You must submit the word that appears in the image.';
}
```

9.1.3 Cookie Helper

The Cookie Helper file contains functions that assist in working with cookies.

Page Contents

- Cookie Helper
 - Loading this Helper
 - set_cookie()
 - get_cookie()
 - delete_cookie()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('cookie');
```

The following functions are available:

set_cookie()

set_cookie (*\$name* = '', *\$value* = '', *\$expire* = '', *\$domain* = '', *\$path* = '/', *\$prefix* = '', *\$secure* = FALSE, *\$httponly* = FALSE)

- **\$name** (*string*) – Cookie name
- **\$value** (*string*) – Cookie value
- **\$expire** (*int*) – Number of seconds until expiration
- **\$domain** (*string*) – Cookie domain (usually: .yourdomain.com)
- **\$path** (*string*) – Cookie path
- **\$prefix** (*string*) – Cookie name prefix
- **\$secure** (*bool*) – Whether to only send the cookie through HTTPS

- **\$httponly** (*bool*) – Whether to hide the cookie from JavaScript

void

This helper function gives you view file friendly syntax to set browser cookies. Refer to the *Input Library* for a description of its use, as this function is an alias for `CI_Input::set_cookie()`.

get_cookie()

get_cookie (*\$index = ''*, *\$xss_clean = FALSE*)

- **\$index** (*string*) – Cookie name
- **\$xss_clean** (*bool*) – Whether to apply XSS filtering to the returned value

mixed

This helper function gives you view file friendly syntax to get browser cookies. Refer to the *Input Library* for a description of its use, as this function is an alias for `CI_Input::cookie()`.

delete_cookie()

delete_cookie (*\$name = ''*, *\$domain = ''*, *\$path = '/'*, *\$prefix = ''*)

- **\$name** (*string*) – Cookie name
- **\$domain** (*string*) – Cookie domain (usually: `.yourdomain.com`)
- **\$path** (*string*) – Cookie path
- **\$prefix** (*string*) – Cookie name prefix

void

Lets you delete a cookie. Unless you've set a custom path or other values, only the name of the cookie is needed.

```
delete_cookie('name');
```

This function is otherwise identical to `set_cookie()`, except that it does not have the value and expiration parameters. You can submit an array of values in the first parameter or you can set discrete parameters.

```
delete_cookie($name, $domain, $path, $prefix)
```

9.1.4 Date Helper

The Date Helper file contains functions that help you work with dates.

Page Contents

- Date Helper
 - Loading this Helper
 - now()
 - mdate()
 - standard_date()
 - * Supported formats
 - local_to_gmt()
 - gmt_to_local()
 - mysql_to_unix()
 - unix_to_human()
 - human_to_unix()
 - nice_date()
 - timespan()
 - days_in_month()
 - date_range()
 - timezones()
 - timezone_menu()
 - Timezone Reference

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('date');
```

The following functions are available:

now()

```
now($timezone = NULL)
```

- **\$timezone** (*string*) – Timezone

int

Returns the current time as a UNIX timestamp, referenced either to your server's local time or any PHP supported timezone, based on the “time reference” setting in your config file. If you do not intend to set your master time reference to any other PHP supported timezone (which you'll typically do if you run a site that lets each user set their own timezone settings) there is no benefit to using this function over PHP's `time()` function.

```
echo now('Australia/Victoria');
```

If a timezone is not provided, it will return `time()` based on the **time_reference** setting.

mdate()

```
mdate($datestr = '', $time = '')
```

- **\$datestr** (*string*) – Date string

- **\$time** (*int*) – UNIX timestamp

int

This function is identical to PHP's `date()` function, except that it lets you use MySQL style date codes, where each code letter is preceded with a percent sign, e.g. `%Y %m %d`

The benefit of doing dates this way is that you don't have to worry about escaping any characters that are not date codes, as you would normally have to do with the `date()` function.

Example:

```
$datestring = 'Year: %Y Month: %m Day: %d - %h:%i %a';
$time = time();
echo mdate($datestring, $time);
```

If a timestamp is not included in the second parameter the current time will be used.

standard_date()

standard_date (*\$fmt* = 'DATE_RFC822', *\$time* = NULL)

- **\$fmt** (*string*) – Date format
- **\$time** (*int*) – UNIX timestamp

string

Lets you generate a date string in one of several standardized formats.

Example:

```
$format = 'DATE_RFC822';
$time = time();
echo standard_date($format, $time);
```

: This function is DEPRECATED. Use the native `date()` combined with [DateTime's format constants](#) instead:

```
echo date(DATE_RFC822, time());
```

Supported formats

Constant	Description	Example
DATE_ATOM	Atom	2005-08-15T16:13:03+0000
DATE_COOKIE	HTTP Cookies	Sun, 14 Aug 2005 16:13:03 UTC
DATE_ISO8601	ISO-8601	2005-08-14T16:13:03+00:00
DATE_RFC822	RFC 822	Sun, 14 Aug 05 16:13:03 UTC
DATE_RFC850	RFC 850	Sunday, 14-Aug-05 16:13:03 UTC
DATE_RFC1036	RFC 1036	Sunday, 14-Aug-05 16:13:03 UTC
DATE_RFC1123	RFC 1123	Sun, 14 Aug 2005 16:13:03 UTC
DATE_RFC2822	RFC 2822	Sun, 14 Aug 2005 16:13:03 +0000
DATE_RSS	RSS	Sun, 14 Aug 2005 16:13:03 UTC
DATE_W3C	W3C	2005-08-14T16:13:03+0000

local_to_gmt()

local_to_gmt (*\$time* = '')

- **\$time** (*int*) – UNIX timestamp

string

Takes a UNIX timestamp as input and returns it as GMT.

Example:

```
$gmt = local_to_gmt(time());
```

gmt_to_local()

gmt_to_local (*\$time* = '', *\$timezone* = 'UTC', *\$dst* = FALSE)

- **\$time** (*int*) – UNIX timestamp
- **\$timezone** (*string*) – Timezone
- **\$dst** (*bool*) – Whether DST is active

int

Takes a UNIX timestamp (referenced to GMT) as input, and converts it to a localized timestamp based on the timezone and Daylight Saving Time submitted.

Example:

```
$timestamp = 1140153693;
$timezone = 'UM8';
$daylight_saving = TRUE;
echo gmt_to_local($timestamp, $timezone, $daylight_saving);
```

: For a list of timezones see the reference at the bottom of this page.

mysql_to_unix()

mysql_to_unix (*\$time* = '')

- **\$time** (*int*) – UNIX timestamp

int

Takes a MySQL Timestamp as input and returns it as a UNIX timestamp.

Example:

```
$unix = mysql_to_unix('20061124092345');
```

unix_to_human()

unix_to_human (*\$time* = '', *\$seconds* = FALSE, *\$fmt* = 'us')

- **\$time** (*int*) – UNIX timestamp
- **\$seconds** (*bool*) – Whether to show seconds
- **\$fmt** (*string*) – format (us or euro)

integer

Takes a UNIX timestamp as input and returns it in a human readable format with this prototype:

```
YYYY-MM-DD HH:MM:SS AM/PM
```

This can be useful if you need to display a date in a form field for submission.

The time can be formatted with or without seconds, and it can be set to European or US format. If only the timestamp is submitted it will return the time without seconds formatted for the U.S.

Examples:

```
$now = time();
echo unix_to_human($now); // U.S. time, no seconds
echo unix_to_human($now, TRUE, 'us'); // U.S. time with seconds
echo unix_to_human($now, TRUE, 'eu'); // Euro time with seconds
```

human_to_unix()

human_to_unix (*\$datestr* = '')

- **\$datestr** (*int*) – Date string

int UNIX timestamp or FALSE on failure

The opposite of the `unix_to_time()` function. Takes a “human” time as input and returns it as a UNIX timestamp. This is useful if you accept “human” formatted dates submitted via a form. Returns boolean FALSE date string passed to it is not formatted as indicated above.

Example:

```
$now = time();  
$human = unix_to_human($now);  
$unix = human_to_unix($human);
```

nice_date()

nice_date (*\$bad_date* = '', *\$format* = FALSE)

- **\$bad_date** (*int*) – The terribly formatted date-like string
- **\$format** (*string*) – Date format to return (same as PHP's `date()` function)

string

This function can take a number poorly-formed date formats and convert them into something useful. It also accepts well-formed dates.

The function will return a UNIX timestamp by default. You can, optionally, pass a format string (the same type as the PHP `date()` function accepts) as the second parameter.

Example:

```
$bad_date = '199605';  
// Should Produce: 1996-05-01  
$better_date = nice_date($bad_date, 'Y-m-d');  
  
$bad_date = '9-11-2001';  
// Should Produce: 2001-09-11  
$better_date = nice_date($bad_date, 'Y-m-d');
```

timespan()

timespan (*\$seconds* = 1, *\$time* = '', *\$units* = '')

- **\$seconds** (*int*) – Number of seconds
- **\$time** (*string*) – UNIX timestamp
- **\$units** (*int*) – Number of time units to display

string

Formats a UNIX timestamp so that it appears similar to this:

```
1 Year, 10 Months, 2 Weeks, 5 Days, 10 Hours, 16 Minutes
```

The first parameter must contain a UNIX timestamp. The second parameter must contain a timestamp that is greater than the first timestamp. The third parameter is optional and limits the number of time units to display.

If the second parameter is empty, the current time will be used.

The most common purpose for this function is to show how much time has elapsed from some point in time in the past to now.

Example:

```
$post_date = '1079621429';
$now = time();
$units = 2;
echo timespan($post_date, $now, $units);
```

: The text generated by this function is found in the following language file: *language/<your_lang>/date_lang.php*

days_in_month()

days_in_month (*\$month* = 0, *\$year* = '')

- **\$month** (*int*) – a numeric month
- **\$year** (*int*) – a numeric year

int

Returns the number of days in a given month/year. Takes leap years into account.

Example:

```
echo days_in_month(06, 2005);
```

If the second parameter is empty, the current year will be used.

date_range()

date_range (*\$unix_start* = '', *\$mixed* = '', *\$is_unix* = TRUE, *\$format* = 'Y-m-d')

- **\$unix_start** (*int*) – UNIX timestamp of the range start date
- **\$mixed** (*int*) – UNIX timestamp of the range end date or interval in days
- **\$is_unix** (*bool*) – set to FALSE if *\$mixed* is not a timestamp
- **\$format** (*string*) – Output date format, same as in `date()`

array

Returns a list of dates within a specified period.

Example:

```
$range = date_range('2012-01-01', '2012-01-15');
echo "First 15 days of 2012:";
foreach ($range as $date)
{
    echo $date."\n";
}
```

timezones()

timezones (*\$tz* = '')

- **\$tz** (*string*) – a numeric timezone

string

Takes a timezone reference (for a list of valid timezones, see the “Timezone Reference” below) and returns the number of hours offset from UTC.

Example:

```
echo timezones('UM5');
```

This function is useful when used with `timezone_menu()`.

timezone_menu()

timezone_menu (*\$default = 'UTC', \$class = '', \$name = 'timezones', \$attributes = ''*)

- **\$default** (*string*) – Timezone
- **\$class** (*string*) – Class name
- **\$name** (*string*) – Menu name
- **\$attributes** (*mixed*) – HTML attributes

string

Generates a pull-down menu of timezones, like this one:

This menu is useful if you run a membership site in which your users are allowed to set their local timezone value.

The first parameter lets you set the “selected” state of the menu. For example, to set Pacific time as the default you will do this:

```
echo timezone_menu('UM8');
```

Please see the timezone reference below to see the values of this menu.

The second parameter lets you set a CSS class name for the menu.

The fourth parameter lets you set one or more attributes on the generated select tag.

: The text contained in the menu is found in the following language file: *language/<your_lang>/date_lang.php*

Timezone Reference

The following table indicates each timezone and its location.

Note some of the location lists have been abridged for clarity and formatting.

	Time Zone	Location
UM12	(UTC - 12:00)	Baker/Howland Island
UM11	(UTC - 11:00)	Samoa Time Zone, Niue
UM10	(UTC - 10:00)	Hawaii-Aleutian Standard Time, Cook Islands
UM95	(UTC - 09:30)	Marquesas Islands
UM9	(UTC - 09:00)	Alaska Standard Time, Gambier Islands
UM8	(UTC - 08:00)	Pacific Standard Time, Clipperton Island
UM7	(UTC - 11:00)	Mountain Standard Time
Continued on next page		

Table 9.1 – continued from previous page

Time Zone	Location
UM6	(UTC - 06:00) Central Standard Time
UM5	(UTC - 05:00) Eastern Standard Time, Western Caribbean
UM45	(UTC - 04:30) Venezuelan Standard Time
UM4	(UTC - 04:00) Atlantic Standard Time, Eastern Caribbean
UM35	(UTC - 03:30) Newfoundland Standard Time
UM3	(UTC - 03:00) Argentina, Brazil, French Guiana, Uruguay
UM2	(UTC - 02:00) South Georgia/South Sandwich Islands
UM1	(UTC - 1:00) Azores, Cape Verde Islands
UTC	(UTC) Greenwich Mean Time, Western European Time
UP1	(UTC +1:00) Central European Time, West Africa Time
UP2	(UTC +2:00) Central Africa Time, Eastern European Time
UP3	(UTC +3:00) Moscow Time, East Africa Time
UP35	(UTC +3:30) Iran Standard Time
UP4	(UTC +4:00) Azerbaijan Standard Time, Samara Time
UP45	(UTC +4:30) Afghanistan
UP5	(UTC +5:00) Pakistan Standard Time, Yekaterinburg Time
UP55	(UTC +5:30) Indian Standard Time, Sri Lanka Time
UP575	(UTC +5:45) Nepal Time
UP6	(UTC +6:00) Bangladesh Standard Time, Bhutan Time, Omsk Time
UP65	(UTC +6:30) Cocos Islands, Myanmar
UP7	(UTC +7:00) Krasnoyarsk Time, Cambodia, Laos, Thailand, Vietnam
UP8	(UTC +8:00) Australian Western Standard Time, Beijing Time

9.1.5 Directory Helper

The Directory Helper file contains functions that assist in working with directories.

Page Contents

- Directory Helper
 - Loading this Helper
 - `directory_map()`

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('directory');
```

The following functions are available:

directory_map()

This function reads the directory path specified in the first parameter and builds an array representation of it and all its contained files.

```
directory_map($source_dir[, $directory_depth = 0[, $hidden = FALSE]])
```

- **\$source_dir** (*string*) – path to the source directory
- **\$directory_depth** (*integer*) – depth of directories to traverse (0 = fully recursive, 1 = current dir, etc)
- **\$hidden** (*boolean*) – whether to include hidden directories

Examples:

```
$map = directory_map('./mydirectory/');
```

: Paths are almost always relative to your main index.php file.

Sub-folders contained within the directory will be mapped as well. If you wish to control the recursion depth, you can do so using the second parameter (integer). A depth of 1 will only map the top level directory:

```
$map = directory_map('./mydirectory/', 1);
```

By default, hidden files will not be included in the returned array. To override this behavior, you may set a third parameter to true (boolean):

```
$map = directory_map('./mydirectory/', FALSE, TRUE);
```

Each folder name will be an array index, while its contained files will be numerically indexed. Here is an example of a typical array:

```
Array (
    [libraries] => Array
        (
            [0] => benchmark.html
            [1] => config.html
            ["database/"] => Array
                (
                    [0] => query_builder.html
                    [1] => binds.html
                    [2] => configuration.html
                    [3] => connecting.html
                    [4] => examples.html
                    [5] => fields.html
                    [6] => index.html
                    [7] => queries.html
                )
            [2] => email.html
            [3] => file_uploading.html
            [4] => image_lib.html
            [5] => input.html
        )
)
```

```

[6] => language.html
[7] => loader.html
[8] => pagination.html
[9] => uri.html
)

```

9.1.6 Download Helper

The Download Helper lets you download data to your desktop.

Page Contents

- Download Helper
 - Loading this Helper
 - force_download()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('download');
```

The following functions are available:

force_download()

```
force_download($filename = '', $data = '', $set_mime = FALSE)
```

- **\$filename** (*string*) – Filename
- **\$data** (*mixed*) – File contents
- **\$set_mime** (*bool*) – Whether to try to send the actual MIME type

void

Generates server headers which force data to be downloaded to your desktop. Useful with file downloads. The first parameter is the **name you want the downloaded file to be named**, the second parameter is the file data.

If you set the second parameter to NULL and \$filename is an existing, readable file path, then its content will be read instead.

If you set the third parameter to boolean TRUE, then the actual file MIME type (based on the filename extension) will be sent, so that if your browser has a handler for that type - it can use it.

Example:

```

$data = 'Here is some text!';
$name = 'mytext.txt';
force_download($name, $data);

```

If you want to download an existing file from your server you'll need to do the following:

```
// Contents of photo.jpg will be automatically read
force_download('/path/to/photo.jpg', NULL);
```

9.1.7 Email Helper

The Email Helper provides some assistive functions for working with Email. For a more robust email solution, see CodeIgniter's *Email Class*.

Page Contents

- Email Helper
 - Loading this Helper
 - `valid_email()`
 - `send_email()`

: The Email helper is DEPRECATED.

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('email');
```

The following functions are available:

`valid_email()`

`valid_email` (*\$email*)

- **`$email`** (*string*) – Email address

bool

Checks if the input is a correctly formatted e-mail address. Note that it doesn't actually prove that the address will be able to receive mail, but simply that it is a validly formed address.

Example:

```
if (valid_email('email@somesite.com'))
{
    echo 'email is valid';
}
else
{
    echo 'email is not valid';
}
```

: All that this function does is to use PHP's native `filter_var()`: `!! (bool) filter_var($email, FILTER_VALIDATE_EMAIL)`;

send_email()

send_email (*\$recipient*, *\$subject*, *\$message*)

- **\$recipient** (*string*) – E-mail address
- **\$subject** (*string*) – Mail subject
- **\$message** (*string*) – Message body

bool

Sends an email using PHP's native [mail\(\)](#) function.

: All that this function does is to use PHP's native `mail: || mail($recipient, $subject, $message);`

For a more robust email solution, see CodeIgniter's *Email Library*.

9.1.8 File Helper

The File Helper file contains functions that assist in working with files.

Page Contents

- File Helper
 - Loading this Helper
 - `read_file()`
 - `write_file()`
 - `delete_files()`
 - `get_filenames()`
 - `get_dir_file_info()`
 - `get_file_info()`
 - `get_mime_by_extension()`
 - `symbolic_permissions()`
 - `octal_permissions()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('file');
```

The following functions are available:

read_file()

read_file (*\$file*)

- **\$file** (*string*) – File path

string or FALSE on failure

Returns the data contained in the file specified in the path.

Example:

```
$string = read_file('./path/to/file.php');
```

The path can be a relative or full server path. Returns FALSE (boolean) on failure.

: The path is relative to your main site index.php file, NOT your controller or view files. CodeIgniter uses a front controller so paths are always relative to the main site index.

: This function is DEPRECATED. Use the native `file_get_contents()` instead.

: If your server is running an **open_basedir** restriction this function might not work if you are trying to access a file above the calling script.

write_file()

write_file(\$path, \$data, \$mode = 'wb')

- **\$path** (*string*) – File path
- **\$data** (*string*) – Data to write to file
- **\$mode** (*string*) – `fopen()` mode

bool

Writes data to the file specified in the path. If the file does not exist then the function will create it.

Example:

```
$data = 'Some file data';
if ( ! write_file('./path/to/file.php', $data) )
{
    echo 'Unable to write the file';
}
else
{
    echo 'File written!';
}
```

You can optionally set the write mode via the third parameter:

```
write_file('./path/to/file.php', $data, 'r+');
```

The default mode is 'wb'. Please see the [PHP user guide](#) for mode options.

: The path is relative to your main site index.php file, NOT your controller or view files. CodeIgniter uses a front controller so paths are always relative to the main site index.

: This function acquires an exclusive lock on the file while writing to it.

delete_files()

delete_files (*\$path*, *\$del_dir* = FALSE, *\$htdocs* = FALSE)

- **\$path** (*string*) – Directory path
- **\$del_dir** (*bool*) – Whether to also delete directories
- **\$htdocs** (*bool*) – Whether to skip deleting .htaccess and index page files

bool

Deletes ALL files contained in the supplied path.

Example:

```
delete_files('./path/to/directory/');
```

If the second parameter is set to TRUE, any directories contained within the supplied root path will be deleted as well.

Example:

```
delete_files('./path/to/directory/', TRUE);
```

: The files must be writable or owned by the system in order to be deleted.

get_filenames()

get_filenames (*\$source_dir*, *\$include_path* = FALSE)

- **\$source_dir** (*string*) – Directory path
- **\$include_path** (*bool*) – Whether to include the path as part of the filenames

array

Takes a server path as input and returns an array containing the names of all files contained within it. The file path can optionally be added to the file names by setting the second parameter to TRUE.

Example:

```
$controllers = get_filenames(APPPATH.'controllers/');
```

get_dir_file_info()

get_dir_file_info (*\$source_dir*, *\$top_level_only*)

- **\$source_dir** (*string*) – Directory path
- **\$top_level_only** (*bool*) – Whether to look only at the specified directory (excluding sub-directories)

array

Reads the specified directory and builds an array containing the filenames, filesize, dates, and permissions. Sub-folders contained within the specified path are only read if forced by sending the second parameter to FALSE, as this can be an intensive operation.

Example:

```
$models_info = get_dir_file_info(APPPATH.'models/');
```

get_file_info()

Given a file and path, returns (optionally) the *name*, *path*, *size* and *date modified* information attributes for a file. Second parameter allows you to explicitly declare what information you want returned.

Valid `$returned_values` options are: *name*, *size*, *date*, *readable*, *writable*, *executable* and *fileperms*.

: The *writable* attribute is checked via PHP's `is_writable()` function, which known to have issues on the IIS webserver. Consider using *fileperms* instead, which returns information from PHP's `fileperms()` function.

get_mime_by_extension()

get_mime_by_extension (*\$filename*)

- **\$filename** (*string*) – File name

string or FALSE on failure

Translates a filename extension into a MIME type based on *config/mimes.php*. Returns FALSE if it can't determine the type, or read the MIME config file.

```
$file = 'somefile.png';  
echo $file.' is has a mime type of '.get_mime_by_extension($file);
```

: This is not an accurate way of determining file MIME types, and is here strictly for convenience. It should not be used for security purposes.

symbolic_permissions()

symbolic_permissions (*\$perms*)

- **\$perms** (*int*) – Permissions

string

Takes numeric permissions (such as is returned by `fileperms()`) and returns standard symbolic notation of file permissions.

```
echo symbolic_permissions(fileperms('./index.php')); // -rw-r--r--
```

octal_permissions()

octal_permissions (*\$perms*)

- **\$perms** (*int*) – Permissions

string

Takes numeric permissions (such as is returned by `fileperms()`) and returns a three character octal notation of file permissions.

```
echo octal_permissions(fileperms('./index.php')); // 644
```

9.1.9 Form Helper

The Form Helper file contains functions that assist in working with forms.

Page Contents

- Form Helper
 - Loading this Helper
 - `form_open()`
 - * Adding Attributes
 - * Adding Hidden Input Fields
 - `form_open_multipart()`
 - `form_hidden()`
 - `form_input()`
 - `form_password()`
 - `form_upload()`
 - `form_textarea()`
 - `form_dropdown()`
 - `form_multiselect()`
 - `form_fieldset()`
 - `form_fieldset_close()`
 - `form_checkbox()`
 - `form_radio()`
 - `form_label()`
 - `form_submit()`
 - `form_reset()`
 - `form_button()`
 - `form_close()`
 - `form_prep()`
 - `set_value()`
 - `set_select()`
 - `set_checkbox()`
 - `set_radio()`
 - `form_error()`
 - `validation_errors()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('form');
```

The following functions are available:

form_open()

```
form_open($action = '', $attributes = '', $hidden = array())
```

- **\$action** (*string*) – Form action/target URI string
- **\$attributes** (*array*) – HTML attributes
- **\$hidden** (*array*) – An array of hidden fields' definitions

string

Creates an opening form tag with a base URL **built from your config preferences**. It will optionally let you add form attributes and hidden input fields, and will always add the *accept-charset* attribute based on the charset value in your config file.

The main benefit of using this tag rather than hard coding your own HTML is that it permits your site to be more portable in the event your URLs ever change.

Here's a simple example:

```
echo form_open('email/send');
```

The above example would create a form that points to your base URL plus the “email/send” URI segments, like this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send">
```

Adding Attributes

Attributes can be added by passing an associative array to the second parameter, like this:

```
$attributes = array('class' => 'email', 'id' => 'myform');  
echo form_open('email/send', $attributes);
```

Alternatively, you can specify the second parameter as a string:

```
echo form_open('email/send', 'class="email" id="myform"');
```

The above examples would create a form similar to this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send" class="email" id="myform">
```

Adding Hidden Input Fields

Hidden fields can be added by passing an associative array to the third parameter, like this:

```
$hidden = array('username' => 'Joe', 'member_id' => '234');  
echo form_open('email/send', '', $hidden);
```

You can skip the second parameter by passing any falsy value to it.

The above example would create a form similar to this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send">
    <input type="hidden" name="username" value="Joe" />
    <input type="hidden" name="member_id" value="234" />
```

form_open_multipart()

form_open_multipart (*\$action* = '', *\$attributes* = array(), *\$hidden* = array())

- **\$action** (*string*) – Form action/target URI string
- **\$attributes** (*array*) – HTML attributes
- **\$hidden** (*array*) – An array of hidden fields' definitions

string

This function is absolutely identical to `form_open()` above, except that it adds a *multipart* attribute, which is necessary if you would like to use the form to upload files with.

form_hidden()

form_hidden (*\$name*, *\$value* = '')

- **\$name** (*string*) – Field name
- **\$value** (*string*) – Field value

string

Lets you generate hidden input fields. You can either submit a name/value string to create one field:

```
form_hidden('username', 'johndoe');
// Would produce: <input type="hidden" name="username" value="johndoe" />
```

... or you can submit an associative array to create multiple fields:

```
$data = array(
    'name'   => 'John Doe',
    'email'  => 'john@example.com',
    'url'    => 'http://example.com'
);

echo form_hidden($data);

/*
    Would produce:
    <input type="hidden" name="name" value="John Doe" />
    <input type="hidden" name="email" value="john@example.com" />
    <input type="hidden" name="url" value="http://example.com" />
*/
```

You can also pass an associative array to the value field:

```
$data = array(
    'name'   => 'John Doe',
    'email'  => 'john@example.com',
```

```
        'url'    => 'http://example.com'
    );

    echo form_hidden('my_array', $data);

    /*
        Would produce:

        <input type="hidden" name="my_array[name]" value="John Doe" />
        <input type="hidden" name="my_array[email]" value="john@example.com" />
        <input type="hidden" name="my_array[url]" value="http://example.com" />
    */
```

If you want to create hidden input fields with extra attributes:

```
$data = array(
    'type'    => 'hidden',
    'name'    => 'email',
    'id'      => 'hiddenemail',
    'value'   => 'john@example.com',
    'class'   => 'hiddenemail'
);

echo form_input($data);

/*
    Would produce:

    <input type="hidden" name="email" value="john@example.com" id="hiddenemail" class="hiddenemail" />
*/
```

form_input()

form_input (*\$data* = '', *\$value* = '', *\$extra* = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard text input field. You can minimally pass the field name and value in the first and second parameter:

```
echo form_input('username', 'johndoe');
```

Or you can pass an associative array containing any data you wish your form to contain:

```
$data = array(
    'name'      => 'username',
    'id'        => 'username',
    'value'     => 'johndoe',
    'maxlength' => '100',
    'size'      => '50',
    'style'     => 'width:50%'
);
```

```
echo form_input($data);
```

```
/*
```

```
    Would produce:
```

```
    <input type="text" name="username" value="johndoe" id="username" maxlength="100" size="50" st
*/
```

If you would like your form to contain some additional data, like JavaScript, you can pass it as a string in the third parameter:

```
$js = 'onClick="some_function()"';
echo form_input('username', 'johndoe', $js);
```

form_password()

```
form_password($data = '', $value = '', $extra = '')
```

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it uses the “password” input type.

form_upload()

```
form_upload($data = '', $value = '', $extra = '')
```

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it uses the “file” input type, allowing it to be used to upload files.

form_textarea()

```
form_textarea($data = '', $value = '', $extra = '')
```

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it generates a “textarea” type.

form_dropdown()

form_dropdown (*\$name* = '', *\$options* = array(), *\$selected* = array(), *\$extra* = '')

- **\$name** (*string*) – Field name
- **\$options** (*array*) – An associative array of options to be listed
- **\$selected** (*array*) – List of fields to mark with the *selected* attribute
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you create a standard drop-down field. The first parameter will contain the name of the field, the second parameter will contain an associative array of options, and the third parameter will contain the value you wish to be selected. You can also pass an array of multiple items through the third parameter, and CodeIgniter will create a multiple select for you.

Example:

```
$options = array(
    'small'      => 'Small Shirt',
    'med'        => 'Medium Shirt',
    'large'      => 'Large Shirt',
    'xlarge'     => 'Extra Large Shirt',
);

$shirts_on_sale = array('small', 'large');
echo form_dropdown('shirts', $options, 'large');

/*
    Would produce:

    <select name="shirts">
        <option value="small">Small Shirt</option>
        <option value="med">Medium Shirt</option>
        <option value="large" selected="selected">Large Shirt</option>
        <option value="xlarge">Extra Large Shirt</option>
    </select>
*/

echo form_dropdown('shirts', $options, $shirts_on_sale);

/*
    Would produce:

    <select name="shirts" multiple="multiple">
        <option value="small" selected="selected">Small Shirt</option>
        <option value="med">Medium Shirt</option>
        <option value="large" selected="selected">Large Shirt</option>
        <option value="xlarge">Extra Large Shirt</option>
    </select>
*/
```

If you would like the opening `<select>` to contain additional data, like an id attribute or JavaScript, you can pass it as a string in the fourth parameter:

```
$js = 'id="shirts" onChange="some_function();"';
echo form_dropdown('shirts', $options, 'large', $js);
```

If the array passed as `$options` is a multidimensional array, then `form_dropdown()` will produce an `<optgroup>` with the array key as the label.

form_multiselect()

```
form_multiselect($name = '', $options = array(), $selected = array(), $extra = '')
```

- **\$name** (*string*) – Field name
- **\$options** (*array*) – An associative array of options to be listed
- **\$selected** (*array*) – List of fields to mark with the *selected* attribute
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you create a standard multiselect field. The first parameter will contain the name of the field, the second parameter will contain an associative array of options, and the third parameter will contain the value or values you wish to be selected.

The parameter usage is identical to using `form_dropdown()` above, except of course that the name of the field will need to use POST array syntax, e.g. `foo[]`.

form_fieldset()

```
form_fieldset($legend_text = '', $attributes = array())
```

- **\$legend_text** (*string*) – Text to put in the `<legend>` tag
- **\$attributes** (*array*) – Attributes to be set on the `<fieldset>` tag

string

Lets you generate fieldset/legend fields.

Example:

```
echo form_fieldset('Address Information');
echo "<p>fieldset content here</p>\n";
echo form_fieldset_close();

/*
    Produces:

        <fieldset>
            <legend>Address Information</legend>
            <p>form content here</p>
        </fieldset>
*/
```

Similar to other functions, you can submit an associative array in the second parameter if you prefer to set additional attributes:

```
$attributes = array(
    'id'      => 'address_info',
    'class'   => 'address_info'
);

echo form_fieldset('Address Information', $attributes);
echo "<p>fieldset content here</p>\n";
echo form_fieldset_close();

/*
    Produces:

    <fieldset id="address_info" class="address_info">
        <legend>Address Information</legend>
        <p>form content here</p>
    </fieldset>
*/
```

form_fieldset_close()

form_fieldset_close (*\$extra* = '')

- **\$extra** (*string*) – Anything to append after the closing tag, *as is*

string

Produces a closing `</fieldset>` tag. The only advantage to using this function is it permits you to pass data to it which will be added below the tag. For example

```
$string = '</div></div>';
echo form_fieldset_close($string);
// Would produce: </fieldset></div></div>
```

form_checkbox()

form_checkbox (*\$data* = '', *\$value* = '', *\$checked* = FALSE, *\$extra* = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$checked** (*bool*) – Whether to mark the checkbox as being *checked*
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a checkbox field. Simple example:

```
echo form_checkbox('newsletter', 'accept', TRUE);
// Would produce: <input type="checkbox" name="newsletter" value="accept" checked="checked" />
```

The third parameter contains a boolean TRUE/FALSE to determine whether the box should be checked or not.

Similar to the other form functions in this helper, you can also pass an array of attributes to the function:

```
$data = array(
    'name'          => 'newsletter',
    'id'            => 'newsletter',
    'value'         => 'accept',
    'checked'       => TRUE,
    'style'         => 'margin:10px'
);

echo form_checkbox($data);
// Would produce: <input type="checkbox" name="newsletter" id="newsletter" value="accept" checked="checked" />
```

Also as with other functions, if you would like the tag to contain additional data like JavaScript, you can pass it as a string in the fourth parameter:

```
$js = 'onClick="some_function()"';
echo form_checkbox('newsletter', 'accept', TRUE, $js)
```

form_radio()

form_radio (\$data = '', \$value = '', \$checked = FALSE, \$extra = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$checked** (*bool*) – Whether to mark the radio button as being *checked*
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_checkbox()` function above except that it uses the “radio” input type.

form_label()

form_label (\$label_text = '', \$id = '', \$attributes = array())

- **\$label_text** (*string*) – Text to put in the <label> tag
- **\$id** (*string*) – ID of the form element that we’re making a label for
- **\$attributes** (*string*) – HTML attributes

string

Lets you generate a <label>. Simple example:

```
echo form_label('What is your Name', 'username');
// Would produce: <label for="username">What is your Name</label>
```

Similar to other functions, you can submit an associative array in the third parameter if you prefer to set additional attributes.

Example:

```
$attributes = array(
    'class' => 'mycustomclass',
    'style' => 'color: #000;'
);

echo form_label('What is your Name', 'username', $attributes);
// Would produce: <label for="username" class="mycustomclass" style="color: #000;">What is your Name
```

form_submit()

form_submit (\$data = '', \$value = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$value** (*string*) – Button value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard submit button. Simple example:

```
echo form_submit('mysubmit', 'Submit Post!');
// Would produce: <input type="submit" name="mysubmit" value="Submit Post!" />
```

Similar to other functions, you can submit an associative array in the first parameter if you prefer to set your own attributes. The third parameter lets you add extra data to your form, like JavaScript.

form_reset()

form_reset (\$data = '', \$value = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$value** (*string*) – Button value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard reset button. Use is identical to `form_submit()`.

form_button()

form_button (\$data = '', \$content = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$content** (*string*) – Button label
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard button element. You can minimally pass the button name and content in the first and second parameter:

```
echo form_button('name', 'content');
// Would produce: <button name="name" type="button">Content</button>
```

Or you can pass an associative array containing any data you wish your form to contain:

```
$data = array(
    'name'      => 'button',
    'id'        => 'button',
    'value'     => 'true',
    'type'      => 'reset',
    'content'   => 'Reset'
);

echo form_button($data);
// Would produce: <button name="button" id="button" value="true" type="reset">Reset</button>
```

If you would like your form to contain some additional data, like JavaScript, you can pass it as a string in the third parameter:

```
$js = 'onClick="some_function()"';
echo form_button('mybutton', 'Click Me', $js);
```

form_close()

form_close(\$extra = '')

- **\$extra** (*string*) – Anything to append after the closing tag, *as is*

string

Produces a closing `</form>` tag. The only advantage to using this function is it permits you to pass data to it which will be added below the tag. For example:

```
$string = '</div></div>';
echo form_close($string);
// Would produce: </form> </div></div>
```

form_prep()

form_prep(\$str = '', \$is_textarea = FALSE)

- **\$str** (*string*) – Value to escape
- **\$is_textarea** (*bool*) – Whether we're preparing for `<textarea>` or a regular input tag

string

Allows you to safely use HTML and characters such as quotes within form elements without breaking out of the form.

Consider this example:

```
$string = 'Here is a string containing "quoted" text.';
<input type="text" name="myform" value="$string" />
```

Since the above string contains a set of quotes it will cause the form to break. The `form_prep()` function converts HTML so that it can be used safely:

```
<input type="text" name="myform" value="<?php echo form_prep($string); ?>" />
```

: If you use any of the form helper functions listed in this page the form values will be prepped automatically, so there is no need to call this function. Use it only if you are creating your own form elements.

set_value()

set_value (*\$field* = '', *\$default* = '', *\$is_textarea* = FALSE)

- **\$field** (*string*) – Field name
- **\$default** (*string*) – Default value
- **\$is_textarea** (*bool*) – Whether we're setting <textarea> content

string

Permits you to set the value of an input form or textarea. You must supply the field name via the first parameter of the function. The second (optional) parameter allows you to set a default value for the form.

Example:

```
<input type="text" name="quantity" value="<?=set_value('quantity', '0');?>" size="50" />
```

The above form will show “0” when loaded for the first time.

set_select()

set_select (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

If you use a <select> menu, this function permits you to display the menu item that was selected.

The first parameter must contain the name of the select menu, the second parameter must contain the value of each item, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<select name="myselect">
    <option value="one" <?php echo set_select('myselect', 'one', TRUE); ?> >One</option>
    <option value="two" <?php echo set_select('myselect', 'two'); ?> >Two</option>
    <option value="three" <?php echo set_select('myselect', 'three'); ?> >Three</option>
</select>
```

set_checkbox()

set_checkbox (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

Permits you to display a checkbox in the state it was submitted.

The first parameter must contain the name of the checkbox, the second parameter must contain its value, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<input type="checkbox" name="mycheck" value="1" <?php echo set_checkbox('mycheck', '1'); ?> />
<input type="checkbox" name="mycheck" value="2" <?php echo set_checkbox('mycheck', '2'); ?> />
```

set_radio()

set_radio (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

Permits you to display radio buttons in the state they were submitted. This function is identical to the `set_checkbox()` function above.

Example:

```
<input type="radio" name="myradio" value="1" <?php echo set_radio('myradio', '1', TRUE); ?> />
<input type="radio" name="myradio" value="2" <?php echo set_radio('myradio', '2'); ?> />
```

: If you are using the Form Validation class, you must always specify a rule for your field, even if empty, in order for the `set_*()` functions to work. This is because if a Form Validation object is defined, the control for `set_*()` is handed over to a method of the class instead of the generic helper function.

form_error()

form_error (*\$field* = '', *\$prefix* = '', *\$suffix* = '')

- **\$field** (*string*) – Field name
- **\$prefix** (*string*) – Error opening tag
- **\$suffix** (*string*) – Error closing tag

string

Returns a validation error message from the *Form Validation Library*, associated with the specified field name. You can optionally specify opening and closing tag(s) to put around the error message.

Example:

```
// Assuming that the 'username' field value was incorrect:
echo form_error('myfield', '<div class="error">', '</div>');

// Would produce: <div class="error">Error message associated with the "username" field.</div>
```

validation_errors()

validation_errors (\$prefix = '', \$suffix = '')

- **\$prefix** (*string*) – Error opening tag
- **\$suffix** (*string*) – Error closing tag

string

Similarly to the `form_error()` function, returns all validation error messages produced by the *Form Validation Library*, with optional opening and closing tags around each of the messages.

Example:

```
echo validation_errors('<span class="error">', '</span>');

/*
    Would produce, e.g.:

    <span class="error">The "email" field doesn't contain a valid e-mail address!</span>
    <span class="error">The "password" field doesn't match the "repeat_password" field!</span>

*/
```

9.1.10 HTML Helper

The HTML Helper file contains functions that assist in working with HTML.

Page Contents

- HTML Helper
 - Loading this Helper
 - `br()`
 - `heading()`
 - `img()`
 - `link_tag()`
 - `nbs()`
 - `ul()` and `ol()`
 - `meta()`
 - `doctype()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('html');
```

The following functions are available:

br()

```
br($count = 1)
```

- **\$count** (*int*) – Number of times to repeat the tag
- string

Generates line break tags (
) based on the number you submit. Example:

```
echo br(3);
```

The above would produce:

heading()

```
heading($data = '', $h = '1', $attributes = '')
```

- **\$data** (*string*) – Content
 - **\$h** (*string*) – Heading level
 - **\$attributes** (*array*) – HTML attributes
- string

Lets you create HTML heading tags. The first parameter will contain the data, the second the size of the heading. Example:

```
echo heading('Welcome!', 3);
```

The above would produce: <h3>Welcome!</h3>

Additionally, in order to add attributes to the heading tag such as HTML classes, ids or inline styles, a third parameter is available:

```
echo heading('Welcome!', 3, 'class="pink"');
```

The above code produces: <h3 class="pink">Welcome!</h3>

img()

```
img($src = '', $index_page = FALSE, $attributes = '')
```

- **\$src** (*string*) – Image source data
- **\$index_page** (*bool*) – Whether to treat \$src as a routed URI string

- **\$attributes** (*array*) – HTML attributes

string

Lets you create HTML `` tags. The first parameter contains the image source. Example:

```
echo img('images/picture.jpg'); // gives 
```

There is an optional second parameter that is a TRUE/FALSE value that specifies if the *src* should have the page specified by `$config['index_page']` added to the address it creates. Presumably, this would be if you were using a media controller:

```
echo img('images/picture.jpg', TRUE); // gives 
```

Additionally, an associative array can be passed to the `img()` function for complete control over all attributes and values. If an *alt* attribute is not provided, CodeIgniter will generate an empty string.

Example:

```
$image_properties = array(
    'src'    => 'images/picture.jpg',
    'alt'    => 'Me, demonstrating how to eat 4 slices of pizza at one time',
    'class'  => 'post_images',
    'width'  => '200',
    'height' => '200',
    'title'  => 'That was quite a night',
    'rel'    => 'lightbox'
);

img($image_properties);
// 
```

link_tag()

link_tag (*\$href* = '', *\$rel* = 'stylesheet', *\$type* = 'text/css', *\$title* = '', *\$media* = '', *\$index_page* = FALSE)

- **\$href** (*string*) – What are we linking to
- **\$rel** (*string*) – Relation type
- **\$type** (*string*) – Type of the related document
- **\$title** (*string*) – Link title
- **\$media** (*string*) – Media type
- **\$index_page** (*bool*) – Whether to treat *\$src* as a routed URI string

string

Lets you create HTML `<link />` tags. This is useful for stylesheet links, as well as other links. The parameters are *href*, with optional *rel*, *type*, *title*, *media* and *index_page*.

index_page is a boolean value that specifies if the *href* should have the page specified by `$config['index_page']` added to the address it creates.

Example:

```
echo link_tag('css/mystyles.css');
// gives <link href="http://site.com/css/mystyles.css" rel="stylesheet" type="text/css" />
```

```
$attributes = array(
    'class' => 'boldlist',
    'id'    => 'mylist'
);

echo ul($list, $attributes);
```

The above code will produce this:

```
<ul class="boldlist" id="mylist">
    <li>red</li>
    <li>blue</li>
    <li>green</li>
    <li>yellow</li>
</ul>
```

Here is a more complex example, using a multi-dimensional array:

```
$attributes = array(
    'class' => 'boldlist',
    'id'    => 'mylist'
);

$list = array(
    'colors' => array(
        'red',
        'blue',
        'green'
    ),
    'shapes' => array(
        'round',
        'square',
        'circles' => array(
            'ellipse',
            'oval',
            'sphere'
        )
    ),
    'moods' => array(
        'happy',
        'upset' => array(
            'defeated' => array(
                'dejected',
                'disheartened',
                'depressed'
            ),
            'annoyed',
            'cross',
            'angry'
        )
    )
);

echo ul($list, $attributes);
```

The above code will produce this:

```
<ul class="boldlist" id="mylist">
    <li>colors
```

```

        <ul>
            <li>red</li>
            <li>blue</li>
            <li>green</li>
        </ul>
    </li>
    <li>shapes
        <ul>
            <li>round</li>
            <li>square</li>
            <li>circles
                <ul>
                    <li>ellipse</li>
                    <li>oval</li>
                    <li>sphere</li>
                </ul>
            </li>
        </ul>
    </li>
    <li>moods
        <ul>
            <li>happy</li>
            <li>upset
                <ul>
                    <li>defeated
                        <ul>
                            <li>dejected</li>
                            <li>disheartened</li>
                            <li>depressed</li>
                        </ul>
                    </li>
                    <li>annoyed</li>
                    <li>cross</li>
                    <li>angry</li>
                </ul>
            </li>
        </ul>
    </li>
</ul>

```

ol (*\$list*, *\$attributes* = '')

- **\$list** (*array*) – List entries
- **\$attributes** (*array*) – HTML attributes

string

Identical to `ul()`, only it produces the `` tag for ordered lists instead of ``.

meta()

meta (*\$name* = '', *\$content* = '', *\$type* = 'name', *\$newline* = "n")

- **\$name** (*string*) – Meta name

- **\$content** (*string*) – Meta content
- **\$type** (*string*) – Meta type
- **\$newline** (*string*) – Newline character

string

Helps you generate meta tags. You can pass strings to the function, or simple arrays, or multidimensional ones.

Examples:

```
echo meta('description', 'My Great site');
// Generates: <meta name="description" content="My Great Site" />

echo meta('Content-type', 'text/html; charset=utf-8', 'equiv');
// Note the third parameter. Can be "equiv" or "name"
// Generates: <meta http-equiv="Content-type" content="text/html; charset=utf-8" />

echo meta(array('name' => 'robots', 'content' => 'no-cache'));
// Generates: <meta name="robots" content="no-cache" />

$meta = array(
    array(
        'name' => 'robots',
        'content' => 'no-cache'
    ),
    array(
        'name' => 'description',
        'content' => 'My Great Site'
    ),
    array(
        'name' => 'keywords',
        'content' => 'love, passion, intrigue, deception'
    ),
    array(
        'name' => 'robots',
        'content' => 'no-cache'
    ),
    array(
        'name' => 'Content-type',
        'content' => 'text/html; charset=utf-8', 'type' => 'equiv'
    )
);

echo meta($meta);
// Generates:
// <meta name="robots" content="no-cache" />
// <meta name="description" content="My Great Site" />
// <meta name="keywords" content="love, passion, intrigue, deception" />
// <meta name="robots" content="no-cache" />
// <meta http-equiv="Content-type" content="text/html; charset=utf-8" />
```

doctype()

doctype (*\$type* = 'xhtml-strict')

- **\$type** (*string*) – Doctype name

Helps you generate document type declarations, or DTD's. XHTML 1.0 Strict is used by default, but many doctypes are available.

Example:

```
echo doctype(); // <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">

echo doctype('html4-trans'); // <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/loose.dtd">
```

The following is a list of doctype choices. These are configurable, and pulled from application/config/doctypes.php

Doctype	Option	Result
XHTML 1.1	doctype('xhtml11')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN" "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
XHTML 1.0 Strict	doctype('xhtml1-strict')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
XHTML 1.0 Transitional	doctype('xhtml1-trans')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
XHTML 1.0 Frameset	doctype('xhtml1-frame')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Frameset//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-frameset.dtd">
XHTML Basic 1.1	doctype('xhtml-basic11')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML Basic 1.1//EN" "http://www.w3.org/TR/xhtml-basic/xhtml-basic11.dtd">
HTML 5	doctype('html5')	<!DOCTYPE html>
HTML 4 Strict	doctype('html4-strict')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/strict.dtd">
HTML 4 Transitional	doctype('html4-trans')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://www.w3.org/TR/html4/loose.dtd">
HTML 4 Frameset	doctype('html4-frame')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Frameset//EN" "http://www.w3.org/TR/html4/frameset.dtd">
MathML 1.01	doctype('mathml1')	<!DOCTYPE math SYSTEM "http://www.w3.org/Math/DTD/mathml1/mathml.dtd">
MathML 2.0	doctype('mathml2')	<!DOCTYPE math PUBLIC "-//W3C//DTD MathML 2.0//EN" "http://www.w3.org/Math/DTD/mathml2/mathml2.dtd">
SVG 1.0	doctype('svg10')	<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.0//EN" "http://www.w3.org/TR/2001/REC-SVG-20010904/DTD/svg10.dtd">
SVG 1.1 Full	doctype('svg11')	<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.1//EN" "http://www.w3.org/Graphics/SVG/1.1/DTD/svg11.dtd">

XHTML+RDFa 1.1	doctype('xhtml-rdfa-2')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML+RDFa 1.1//EN" "http://www.w3.org/MarkUp/DTD/xhtml-rdfa-2.dtd">

9.1.11 Inflector Helper

The Inflector Helper file contains functions that permits you to change words to plural, singular, camel case, etc.

Page Contents

- Inflector Helper
 - Loading this Helper
 - singular()
 - plural()
 - camelize()
 - underscore()
 - humanize()
 - is_countable()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('inflector');
```

The following functions are available:

singular()

singular (*\$str*)

- **\$str** (*string*) – Input string
string

Changes a plural word to singular. Example:

```
echo singular('dogs'); // Prints 'dog'
```

plural()

plural (*\$str*)

- **\$str** (*string*) – Input string
string

Changes a singular word to plural. Example:

```
echo plural('dog'); // Prints 'dogs'
```

camelize()

camelize (*\$str*)

- **\$str** (*string*) – Input string

string

Changes a string of words separated by spaces or underscores to camel case. Example:

```
echo camelize('my_dog_spot'); // Prints 'myDogSpot'
```

underscore()

camelize (*\$str*)

- **\$str** (*string*) – Input string

string

Takes multiple words separated by spaces and underscores them. Example:

```
echo underscore('my dog spot'); // Prints 'my_dog_spot'
```

humanize()

camelize (*\$str*)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Input separator

string

Takes multiple words separated by underscores and adds spaces between them. Each word is capitalized.

Example:

```
echo humanize('my_dog_spot'); // Prints 'My Dog Spot'
```

To use dashes instead of underscores:

```
echo humanize('my-dog-spot', '-'); // Prints 'My Dog Spot'
```

is_countable()

is_countable (*\$word*)

- **\$word** (*string*) – Input string

bool

Checks if the given word has a plural version. Example:

```
is_countable('equipment'); // Returns FALSE
```

9.1.12 Language Helper

The Language Helper file contains functions that assist in working with language files.

Page Contents

- Language Helper
 - Loading this Helper
 - lang()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('language');
```

The following functions are available:

lang()

lang (*\$line*, *\$for* = '', *\$attributes* = array())

- **\$line** (*string*) – Language line key
- **\$for** (*string*) – HTML “for” attribute (ID of the element we’re creating a label for)
- **\$attributes** (*array*) – Any additional HTML attributes

string

This function returns a line of text from a loaded language file with simplified syntax that may be more desirable for view files than `CI_Lang::line()`.

Example:

```
echo lang('language_key', 'form_item_id', array('class' => 'myClass'));  
// Outputs: <label for="form_item_id" class="myClass">Language line</label>
```

9.1.13 Number Helper

The Number Helper file contains functions that help you work with numeric data.

Page Contents

- Number Helper
 - Loading this Helper
 - byte_format()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('number');
```

The following functions are available:

byte_format()

byte_format (*\$num*, *\$precision = 1*)

- **\$num** (*mixed*) – Number of bytes
 - **\$precision** (*int*) – Floating point precision
- string

Formats numbers as bytes, based on size, and adds the appropriate suffix. Examples:

```
echo byte_format(456); // Returns 456 Bytes
echo byte_format(4567); // Returns 4.5 KB
echo byte_format(45678); // Returns 44.6 KB
echo byte_format(456789); // Returns 447.8 KB
echo byte_format(3456789); // Returns 3.3 MB
echo byte_format(12345678912345); // Returns 1.8 GB
echo byte_format(123456789123456789); // Returns 11,228.3 TB
```

An optional second parameter allows you to set the precision of the result:

```
echo byte_format(45678, 2); // Returns 44.61 KB
```

: The text generated by this function is found in the following language file: *language/<your_lang>/number_lang.php*

9.1.14 Path Helper

The Path Helper file contains functions that permits you to work with file paths on the server.

Page Contents

- Path Helper
 - Loading this Helper
 - set_realpath()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('path');
```

The following functions are available:

set_realpath()

set_realpath(\$path, \$check_existence = FALSE)

- **\$path** (*string*) – Path
- **\$check_existence** (*bool*) – Whether to check if the path actually exists

string

This function will return a server path without symbolic links or relative directory structures. An optional second argument will cause an error to be triggered if the path cannot be resolved.

Examples:

```
$file = '/etc/php5/apache2/php.ini';  
echo set_realpath($file); // Prints '/etc/php5/apache2/php.ini'
```

```
$non_existent_file = '/path/to/non-exist-file.txt';  
echo set_realpath($non_existent_file, TRUE); // Shows an error, as the path cannot be resolved  
echo set_realpath($non_existent_file, FALSE); // Prints '/path/to/non-exist-file.txt'
```

```
$directory = '/etc/php5';  
echo set_realpath($directory); // Prints '/etc/php5/'
```

```
$non_existent_directory = '/path/to/nowhere';  
echo set_realpath($non_existent_directory, TRUE); // Shows an error, as the path cannot be resolved  
echo set_realpath($non_existent_directory, FALSE); // Prints '/path/to/nowhere'
```

9.1.15 Security Helper

The Security Helper file contains security related functions.

Page Contents

- Security Helper
 - Loading this Helper
 - xss_clean()
 - sanitize_filename()
 - do_hash()
 - strip_image_tags()
 - encode_php_tags()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('security');
```

The following functions are available:

xss_clean()

xss_clean (\$str, \$is_image = FALSE)

- **\$str** (*string*) – Input data
- **\$is_image** (*bool*) – Whether we’re dealing with an image

string

Provides Cross Site Script Hack filtering.

This function is an alias for `CI_Input::xss_clean()`. For more info, please see the *Input Library* documentation.

sanitize_filename()

sanitize_filename (\$filename)

- **\$filename** (*string*) – Filename

string

Provides protection against directory traversal.

This function is an alias for `CI_Security::sanitize_filename()`. For more info, please see the *Security Library* documentation.

do_hash()

do_hash (\$str, \$type = 'sha1')

- **\$str** (*string*) – Input
- **\$type** (*string*) – Algorithm

string

Permits you to create one way hashes suitable for encrypting passwords. Will use SHA1 by default.

See [hash_algos\(\)](#) for a full list of supported algorithms.

Examples:

```
$str = do_hash($str); // SHA1
$str = do_hash($str, 'md5'); // MD5
```

: This function was formerly named `dohash()`, which has been removed in favor of `do_hash()`.

: This function is DEPRECATED. Use the native `hash()` instead.

strip_image_tags()

strip_image_tags (\$str)

- **\$str** (*string*) – Input

string

This is a security function that will strip image tags from a string. It leaves the image URL as plain text.

Example:

```
$string = strip_image_tags($string);
```

This function is an alias for `CI_Security::strip_image_tags()`. For more info, please see the *Security Library* documentation.

encode_php_tags()

encode_php_tags (\$str)

- **\$str** (*string*) – Input

string

This is a security function that converts PHP tags to entities.

Example:

```
$string = encode_php_tags($string);
```

9.1.16 Smiley Helper

The Smiley Helper file contains functions that let you manage smileys (emoticons).

Page Contents

- Smiley Helper
 - Loading this Helper
 - Overview
 - Clickable Smileys Tutorial
 - * The Controller
 - * Field Aliases
 - get_clickable_smileys()
 - smiley_js()
 - parse_smileys()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('smiley');
```

Overview

The Smiley helper has a renderer that takes plain text smileys, like :-), and turns them into a image representation, like . It also lets you display a set of smiley images that when clicked will be inserted into a form field. For example, if you have a blog that allows user commenting you can show the smileys next to the comment form. Your users can click a desired smiley and with the help of some JavaScript it will be placed into the form field.

Clickable Smileys Tutorial

Here is an example demonstrating how you might create a set of clickable smileys next to a form field. This example requires that you first download and install the smiley images, then create a controller and the View as described.

: Before you begin, please [download the smiley images](#) and put them in a publicly accessible place on your server. This helper also assumes you have the smiley replacement array located at *application/config/smileys.php*

The Controller

In your **application/controllers/** directory, create a file called **Smileys.php** and place the code below in it.

: Change the URL in the `get_clickable_smileys()` function below so that it points to your smiley folder.

You'll notice that in addition to the smiley helper, we are also using the *Table Class*:

```
<?php
```

```
class Smileys extends CI_Controller {

    public function index()
    {
        $this->load->helper('smiley');
        $this->load->library('table');

        $image_array = get_clickable_smileys('http://example.com/images/smileys/', 'comments');
        $col_array = $this->table->make_columns($image_array, 8);

        $data['smiley_table'] = $this->table->generate($col_array);
        $this->load->view('smiley_view', $data);
    }

}
```

In your **application/views/** folder, create a file called **smiley_view.php** and place this code in it:

```
<html>
    <head>
        <title>Smileys</title>
        <?php echo smiley_js(); ?>
    </head>
    <body>
        <form name="blog">
```

```
                <textarea name="comments" id="comments" cols="40" rows="4"></textarea>
            </form>
            <p>Click to insert a smiley!</p>
            <?php echo $smiley_table; ?> </body> </html>
        When you have created the above controller and view, load it by visiting http://www.
    </body>
</html>
```

Field Aliases

When making changes to a view it can be inconvenient to have the field id in the controller. To work around this, you can give your smiley links a generic name that will be tied to a specific id in your view.

```
$image_array = get_smiley_links("http://example.com/images/smileys/", "comment_textarea_alias");
```

To map the alias to the field id, pass them both into the `smiley_js()` function:

```
$image_array = smiley_js("comment_textarea_alias", "comments");
```

get_clickable_smileys()

get_clickable_smileys (*\$image_url*, *\$alias* = '', *\$smileys* = NULL)

- **\$image_url** (*string*) – URL path to the smileys directory
- **\$alias** (*string*) – Field alias

array

Returns an array containing your smiley images wrapped in a clickable link. You must supply the URL to your smiley folder and a field id or field alias.

Example:

```
$image_array = get_smiley_links("http://example.com/images/smileys/", "comment");
```

smiley_js()

smiley_js (*\$alias* = '', *\$field_id* = '', *\$inline* = TRUE)

- **\$alias** (*string*) – Field alias
- **\$field_id** (*string*) – Field ID
- **\$inline** (*bool*) – Whether we're inserting an inline smiley

Generates the JavaScript that allows the images to be clicked and inserted into a form field. If you supplied an alias instead of an id when generating your smiley links, you need to pass the alias and corresponding form id into the function. This function is designed to be placed into the `<head>` area of your web page.

Example:

```
<?php echo smiley_js(); ?>
```

parse_smileys()

parse_smileys (*\$str* = '', *\$image_url* = '', *\$smileys* = *NULL*)

- **\$str** (*string*) – Text containing smiley codes
- **\$image_url** (*string*) – URL path to the smileys directory
- **\$smileys** (*array*) – An array of smileys

string

Takes a string of text as input and replaces any contained plain text smileys into the image equivalent. The first parameter must contain your string, the second must contain the URL to your smiley folder

Example:

```
$str = 'Here are some smileys: :-) ;-)';
$str = parse_smileys($str, "http://example.com/images/smileys/");
echo $str;
```

9.1.17 String Helper

The String Helper file contains functions that assist in working with strings.

Page Contents

- String Helper
 - Loading this Helper
 - random_string()
 - increment_string()
 - alternator()
 - repeater()
 - reduce_double_slashes()
 - strip_slashes()
 - trim_slashes()
 - reduce_multiples()
 - quotes_to_entities()
 - strip_quotes()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('string');
```

The following functions are available:

random_string()

random_string (*\$type* = 'alnum', *\$len* = 8)

- **\$type** (*string*) – Randomization type
- **\$len** (*int*) – Output string length

string

Generates a random string based on the type and length you specify. Useful for creating passwords or generating random hashes.

The first parameter specifies the type of string, the second parameter specifies the length. The following choices are available:

- **alpha**: A string with lower and uppercase letters only.
- **alnum**: Alpha-numeric string with lower and uppercase characters.
- **basic**: A random number based on `mt_rand()`.
- **numeric**: Numeric string.
- **nozero**: Numeric string with no zeros.
- **md5**: An encrypted random number based on `md5()` (fixed length of 32).
- **sha1**: An encrypted random number based on `sha1()` (fixed length of 40).

Usage example:

```
echo random_string('alnum', 16);
```

: Usage of the *unique* and *encrypt* types is DEPRECATED. They are just aliases for *md5* and *sha1* respectively.

increment_string()

increment_string (*\$str*, *\$separator* = `'_'`, *\$first* = `1`)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Separator to append a duplicate number with
- **\$first** (*int*) – Starting number

string

Increments a string by appending a number to it or increasing the number. Useful for creating “copies” or a file or duplicating database content which has unique titles or slugs.

Usage example:

```
echo increment_string('file', '_'); // "file_1"
echo increment_string('file', '- ', 2); // "file-2"
echo increment_string('file_4'); // "file_5"
```

alternator()

alternator (*\$args*)

- **\$args** (*mixed*) – A variable number of arguments

mixed

Allows two or more items to be alternated between, when cycling through a loop. Example:

```

for ($i = 0; $i < 10; $i++)
{
    echo alternator('string one', 'string two');
}

```

You can add as many parameters as you want, and with each iteration of your loop the next item will be returned.

```

for ($i = 0; $i < 10; $i++)
{
    echo alternator('one', 'two', 'three', 'four', 'five');
}

```

: To use multiple separate calls to this function simply call the function with no arguments to re-initialize.

repeater()

repeater (*\$data*, *\$num* = 1)

- **\$data** (*string*) – Input
- **\$num** (*int*) – Number of times to repeat

string

Generates repeating copies of the data you submit. Example:

```

$string = "\n";
echo repeater($string, 30);

```

The above would generate 30 newlines.

: This function is DEPRECATED. Use the native `str_repeat()` instead.

reduce_double_slashes()

reduce_double_slashes (*\$str*)

- **\$str** (*string*) – Input string

string

Converts double slashes in a string to a single slash, except those found in URL protocol prefixes (e.g. <http://>).

Example:

```

$string = "http://example.com//index.php";
echo reduce_double_slashes($string); // results in "http://example.com/index.php"

```

strip_slashes()

strip_slashes (*\$data*)

- **\$data** (*array*) – Input

array

Removes any slashes from an array of strings.

Example:

```
$str = array(
    'question' => 'Is your name O\'reilly?',
    'answer' => 'No, my name is O\'connor.'
);

$str = strip_slashes($str);
```

The above will return the following array:

```
array(
    'question' => "Is your name O'reilly?",
    'answer' => "No, my name is O'connor."
);
```

: For historical reasons, this function will also accept and handle string inputs. This however makes it just an alias for `stripslashes()`.

trim_slashes()

trim_slashes (*\$str*)

- **\$str** (*string*) – Input string

string

Removes any leading/trailing slashes from a string. Example:

```
$string = "/this/that/theother/";
echo trim_slashes($string); // results in this/that/theother
```

: This function is DEPRECATED. Use the native `trim()` instead: `|| trim($str, '/')`;

reduce_multiples()

reduce_multiples (*\$str*, *\$character* = `'`, *\$trim* = *FALSE*)

- **\$str** (*string*) – Text to search in
- **\$character** (*string*) – Character to reduce
- **\$trim** (*bool*) – Whether to also trim the specified character

string

Reduces multiple instances of a particular character occurring directly after each other. Example:

```
$string = "Fred, Bill,, Joe, Jimmy";
$string = reduce_multiples($string, ","); //results in "Fred, Bill, Joe, Jimmy"
```

If the third parameter is set to TRUE it will remove occurrences of the character at the beginning and the end of the string. Example:

```
$string = ",Fred, Bill,, Joe, Jimmy,";
$string = reduce_multiples($string, " ", TRUE); //results in "Fred, Bill, Joe, Jimmy"
```

quotes_to_entities()

quotes_to_entities (\$str)

- **\$str** (*string*) – Input string

string

Converts single and double quotes in a string to the corresponding HTML entities. Example:

```
$string = "Joe's \"dinner\"";
$string = quotes_to_entities($string); //results in "Joe&#39;s &quot;dinner&quot;"
```

strip_quotes()

strip_quotes (\$str)

- **\$str** (*string*) – Input string

string

Removes single and double quotes from a string. Example:

```
$string = "Joe's \"dinner\"";
$string = strip_quotes($string); //results in "Joes dinner"
```

9.1.18 Text Helper

The Text Helper file contains functions that assist in working with text.

Page Contents

- Text Helper
 - Loading this Helper
 - word_limiter()
 - character_limiter()
 - ascii_to_entities()
 - entities_to_ascii()
 - convert_accented_characters()
 - word_censor()
 - highlight_code()
 - highlight_phrase()
 - word_wrap()
 - ellipsis()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('text');
```

The following functions are available:

word_limiter()

word_limiter (*\$str*, *\$limit* = 100, *\$end_char* = '…')

- **\$str** (*string*) – Input string
- **\$limit** (*int*) – Limit
- **\$end_char** (*string*) – End character (usually an ellipsis)

string

Truncates a string to the number of *words* specified. Example:

```
$string = "Here is a nice text string consisting of eleven words.";
$string = word_limiter($string, 4);
// Returns: Here is a nice...
```

The third parameter is an optional suffix added to the string. By default it adds an ellipsis.

character_limiter()

character_limiter (*\$str*, *\$n* = 500, *\$end_char* = '…')

- **\$str** (*string*) – Input string
- **\$n** (*int*) – Number of characters
- **\$end_char** (*string*) – End character (usually an ellipsis)

string

Truncates a string to the number of *characters* specified. It maintains the integrity of words so the character count may be slightly more or less than what you specify.

Example:

```
$string = "Here is a nice text string consisting of eleven words.";
$string = character_limiter($string, 20);
// Returns: Here is a nice text string...
```

The third parameter is an optional suffix added to the string, if undeclared this helper uses an ellipsis.

: If you need to truncate to an exact number of characters please see the *ellipsesize()* function below.

ascii_to_entities()

ascii_to_entities (\$str)

- **\$str** (*string*) – Input string

string

Converts ASCII values to character entities, including high ASCII and MS Word characters that can cause problems when used in a web page, so that they can be shown consistently regardless of browser settings or stored reliably in a database. There is some dependence on your server's supported character sets, so it may not be 100% reliable in all cases, but for the most part it should correctly identify characters outside the normal range (like accented characters).

Example:

```
$string = ascii_to_entities($string);
```

entities_to_ascii()

This function does the opposite of `ascii_to_entities()`. It turns character entities back into ASCII.

convert_accented_characters()

convert_accented_characters (\$str)

- **\$str** (*string*) – Input string

string

Transliterates high ASCII characters to low ASCII equivalents. Useful when non-English characters need to be used where only standard ASCII characters are safely used, for instance, in URLs.

Example:

```
$string = convert_accented_characters($string);
```

: This function uses a companion config file *application/config/foreign_chars.php* to define the to and from array for transliteration.

word_censor()

word_censor (*\$str*, *\$censored*, *\$replacement* = '')

- **\$str** (*string*) – Input string
- **\$censored** (*array*) – List of bad words to censor
- **\$replacement** (*string*) – What to replace bad words with

string

Enables you to censor words within a text string. The first parameter will contain the original string. The second will contain an array of words which you disallow. The third (optional) parameter can contain a replacement value for the words. If not specified they are replaced with pound signs: #####.

Example:

```
$disallowed = array('darn', 'shucks', 'golly', 'phooey');  
$string = word_censor($string, $disallowed, 'Beep!');
```

highlight_code()

highlight_code (*\$str*)

- **\$str** (*string*) – Input string

string

Colorizes a string of code (PHP, HTML, etc.). Example:

```
$string = highlight_code($string);
```

The function uses PHP's `highlight_string()` function, so the colors used are the ones specified in your `php.ini` file.

highlight_phrase()

highlight_phrase (*\$str*, *\$phrase*, *\$tag_open* = '', *\$tag_close* = '')

- **\$str** (*string*) – Input string
- **\$phrase** (*string*) – Phrase to highlight
- **\$tag_open** (*string*) – Opening tag used for the highlight
- **\$tag_close** (*string*) – Closing tag for the highlight

string

Will highlight a phrase within a text string. The first parameter will contain the original string, the second will contain the phrase you wish to highlight. The third and fourth parameters will contain the opening/closing HTML tags you would like the phrase wrapped in.

Example:

```
$string = "Here is a nice text string about nothing in particular.";
echo highlight_phrase($string, "nice text", '<span style="color:#990000;">', '</span>');
```

The above code prints:

```
Here is a <span style="color:#990000;">nice text</span> string about nothing in particular.
```

word_wrap()

```
word_wrap($str, $charlim = 76)
```

- **\$str** (*string*) – Input string
- **\$charlim** (*int*) – Character limit

string

Wraps text at the specified *character* count while maintaining complete words.

Example:

```
$string = "Here is a simple string of text that will help us demonstrate this function.";
echo word_wrap($string, 25);

// Would produce: Here is a simple string of text that will help us demonstrate this function
```

ellipsesize()

```
ellipsesize($str, $max_length, $position = 1, $ellipsis = '&hellip;')
```

- **\$str** (*string*) – Input string
- **\$max_length** (*int*) – String length limit
- **\$position** (*mixed*) – Position to split at (int or float)
- **\$ellipsis** (*string*) – What to use as the ellipsis character

string

This function will strip tags from a string, split it at a defined maximum length, and insert an ellipsis.

The first parameter is the string to ellipsesize, the second is the number of characters in the final string. The third parameter is where in the string the ellipsis should appear from 0 - 1, left to right. For example, a value of 1 will place the ellipsis at the right of the string, .5 in the middle, and 0 at the left.

An optional forth parameter is the kind of ellipsis. By default, … will be inserted.

Example:

```
$str = 'this_string_is_entirely_too_long_and_might_break_my_design.jpg';
echo ellipsesize($str, 32, .5);
```

Produces:

```
this_string_is_e&hellip;ak_my_design.jpg
```

9.1.19 Typography Helper

The Typography Helper file contains functions that help you format text in semantically relevant ways.

Page Contents

- Typography Helper
 - Loading this Helper
 - `auto_typography()`
 - `nl2br_except_pre()`
 - `entity_decode()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('typography');
```

The following functions are available:

`auto_typography()`

`auto_typography` (*\$str*, *\$reduce_linebreaks* = *FALSE*)

- **`$str`** (*string*) – Input string
- **`$reduce_linebreaks`** (*bool*) – Whether to reduce multiple instances of double newlines to two

string

Formats text so that it is semantically and typographically correct HTML.

This function is an alias for `CI_Typography::auto_typography`. For more info, please see the *Typography Library* documentation.

Usage example:

```
$string = auto_typography($string);
```

: Typographic formatting can be processor intensive, particularly if you have a lot of content being formatted. If you choose to use this function you may want to consider *caching* [<../general/caching>](#) your pages.

`nl2br_except_pre()`

`nl2br_except_pre` (*\$str*)

- **`$str`** (*string*) – Input string

string

Converts newlines to `
` tags unless they appear within `<pre>` tags. This function is identical to the native PHP `nl2br()` function, except that it ignores `<pre>` tags.

Usage example:

```
$string = nl2br_except_pre($string);
```

entity_decode()

entity_decode (*\$str*, *\$charset* = *NULL*)

- **\$str** (*string*) – Input string
- **\$charset** (*string*) – Character set

string

This function is an alias for `CI_Security::entity_decode()`. For more info, please see the *Security Library* documentation.

9.1.20 URL Helper

The URL Helper file contains functions that assist in working with URLs.

Page Contents

- URL Helper
 - Loading this Helper
 - `site_url()`
 - `base_url()`
 - `current_url()`
 - `uri_string()`
 - `index_page()`
 - `anchor()`
 - `anchor_popup()`
 - `mailto()`
 - `safe_mailto()`
 - `auto_link()`
 - `url_title()`
 - * `prep_url()`
 - `redirect()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('url');
```

The following functions are available:

site_url()

```
site_url ($uri = '', $protocol = NULL)
```

- **\$uri** (*string*) – URI string
- **\$protocol** (*string*) – Protocol, e.g. 'http' or 'https'

string

Returns your site URL, as specified in your config file. The `index.php` file (or whatever you have set as your site **index_page** in your config file) will be added to the URL, as will any URI segments you pass to the function, plus the **url_suffix** as set in your config file.

You are encouraged to use this function any time you need to generate a local URL so that your pages become more portable in the event your URL changes.

Segments can be optionally passed to the function as a string or an array. Here is a string example:

```
echo site_url('news/local/123');
```

The above example would return something like: *http://example.com/index.php/news/local/123*

Here is an example of segments passed as an array:

```
$segments = array('news', 'local', '123');  
echo site_url($segments);
```

This function is an alias for `CI_Config::site_url()`. For more info, please see the *Config Library* documentation.

base_url()

```
base_url ($uri = '', $protocol = NULL)
```

- **\$uri** (*string*) – URI string
- **\$protocol** (*string*) – Protocol, e.g. 'http' or 'https'

string

Returns your site base URL, as specified in your config file. Example:

```
echo base_url();
```

This function returns the same thing as `site_url()`, without the *index_page* or *url_suffix* being appended.

Also like `site_url()`, you can supply segments as a string or an array. Here is a string example:

```
echo base_url("blog/post/123");
```

The above example would return something like: *http://example.com/blog/post/123*

This is useful because unlike `site_url()`, you can supply a string to a file, such as an image or stylesheet. For example:

```
echo base_url("images/icons/edit.png");
```

This would give you something like: *http://example.com/images/icons/edit.png*

This function is an alias for `CI_Config::base_url()`. For more info, please see the *Config Library* documentation.

current_url()

current_url()

string

Returns the full URL (including segments) of the page being currently viewed.

: Calling this function is the same as doing this: `|| site_url(uri_string());`

uri_string()

uri_string()

string

Returns the URI segments of any page that contains this function. For example, if your URL was this:

`http://some-site.com/blog/comments/123`

The function would return:

`blog/comments/123`

This function is an alias for `CI_Config::uri_string()`. For more info, please see the *Config Library* documentation.

index_page()

index_page()

string

Returns your site **index_page**, as specified in your config file. Example:

`echo index_page();`

anchor()

anchor (*\$uri* = '', *\$title* = '', *\$attributes* = '')

- **\$uri** (*string*) – URI string
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Creates a standard HTML anchor link based on your local site URL.

The first parameter can contain any segments you wish appended to the URL. As with the `site_url()` function above, segments can be a string or an array.

: If you are building links that are internal to your application do not include the base URL (<http://...>). This will be added automatically from the information specified in your config file. Include only the URI segments you wish appended to the URL.

The second segment is the text you would like the link to say. If you leave it blank, the URL will be used.

The third parameter can contain a list of attributes you would like added to the link. The attributes can be a simple string or an associative array.

Here are some examples:

```
echo anchor('news/local/123', 'My News', 'title="News title"');
// Prints: <a href="http://example.com/index.php/news/local/123" title="News title">My News</a>

echo anchor('news/local/123', 'My News', array('title' => 'The best news!'));
// Prints: <a href="http://example.com/index.php/news/local/123" title="The best news!">My News</a>

echo anchor('', 'Click here');
// Prints: <a href="http://example.com">Click Here</a>
```

anchor_popup()

anchor_popup (*\$uri* = '', *\$title* = '', *\$attributes* = FALSE)

- **\$uri** (*string*) – URI string
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Nearly identical to the `:php:func:anchor()` function except that it opens the URL in a new window. You can specify JavaScript window attributes in the third parameter to control how the window is opened. If the third parameter is not set it will simply open a new window with your own browser settings.

Here is an example with attributes:

```
$atts = array(
    'width'      => 800,
    'height'     => 600,
    'scrollbars' => 'yes',
    'status'     => 'yes',
    'resizable'  => 'yes',
    'screenx'    => 0,
    'screeny'    => 0,
    'window_name' => '_blank'
);

echo anchor_popup('news/local/123', 'Click Me!', $atts);
```

: The above attributes are the function defaults so you only need to set the ones that are different from what you

need. If you want the function to use all of its defaults simply pass an empty array in the third parameter: `|| echo anchor_popup('news/local/123', 'Click Me!', array());`

: The **window_name** is not really an attribute, but an argument to the JavaScript `window.open()` `<http://www.w3schools.com/jsref/met_win_open.asp>` method, which accepts either a window name or a window target.

: Any other attribute than the listed above will be parsed as an HTML attribute to the anchor tag.

mailto()

mailto(\$email, \$title = '', \$attributes = '')

- **\$email** (*string*) – E-mail address
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Creates a standard HTML e-mail link. Usage example:

```
echo mailto('me@my-site.com', 'Click Here to Contact Me');
```

As with the `anchor()` tab above, you can set attributes using the third parameter:

```
$attributes = array('title' => 'Mail me');
echo mailto('me@my-site.com', 'Contact Me', $attributes);
```

safe_mailto()

safe_mailto(\$email, \$title = '', \$attributes = '')

- **\$email** (*string*) – E-mail address
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Identical to the `mailto()` function except it writes an obfuscated version of the *mailto* tag using ordinal numbers written with JavaScript to help prevent the e-mail address from being harvested by spam bots.

auto_link()

auto_link(\$str, \$type = 'both', \$popup = FALSE)

- **\$str** (*string*) – Input string
- **\$type** (*string*) – Link type ('email', 'url' or 'both')

- **\$popup** (*bool*) – Whether to create popup links

string

Automatically turns URLs and e-mail addresses contained in a string into links. Example:

```
$string = auto_link($string);
```

The second parameter determines whether URLs and e-mails are converted or just one or the other. Default behavior is both if the parameter is not specified. E-mail links are encoded as `safe_mailto()` as shown above.

Converts only URLs:

```
$string = auto_link($string, 'url');
```

Converts only e-mail addresses:

```
$string = auto_link($string, 'email');
```

The third parameter determines whether links are shown in a new window. The value can be TRUE or FALSE (boolean):

```
$string = auto_link($string, 'both', TRUE);
```

url_title()

url_title (*\$str*, *\$separator* = '-', *\$lowercase* = FALSE)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Word separator
- **\$lowercase** (*string*) – Whether to transform the output string to lower-case

string

Takes a string as input and creates a human-friendly URL string. This is useful if, for example, you have a blog in which you'd like to use the title of your entries in the URL. Example:

```
$title = "What's wrong with CSS?";  
$url_title = url_title($title);  
// Produces: Whats-wrong-with-CSS
```

The second parameter determines the word delimiter. By default dashes are used. Preferred options are: - (dash) or _ (underscore)

Example:

```
$title = "What's wrong with CSS?";  
$url_title = url_title($title, 'underscore');  
// Produces: Whats_wrong_with_CSS
```

: Old usage of 'dash' and 'underscore' as the second parameter is DEPRECATED.

The third parameter determines whether or not lowercase characters are forced. By default they are not. Options are boolean TRUE/FALSE.

Example:

```
$title = "What's wrong with CSS?";
$url_title = url_title($title, 'underscore', TRUE);
// Produces: whats_wrong_with_css
```

prep_url()

```
prep_url($str = '')
```

- **\$str** (*string*) – URL string

string

This function will add <http://> in the event that a protocol prefix is missing from a URL.

Pass the URL string to the function like this:

```
$url = prep_url('example.com');
```

redirect()

```
redirect($uri = '', $method = 'auto', $code = NULL)
```

- **\$uri** (*string*) – URI string
- **\$method** (*string*) – Redirect method ('auto', 'location' or 'refresh')
- **\$code** (*string*) – HTTP Response code (usually 302 or 303)

void

Does a “header redirect” to the URI specified. If you specify the full site URL that link will be built, but for local links simply providing the URI segments to the controller you want to direct to will create the link. The function will build the URL based on your config file values.

The optional second parameter allows you to force a particular redirection method. The available methods are **auto**, **location** and **refresh**, with location being faster but less reliable on IIS servers. The default is **auto**, which will attempt to intelligently choose the method based on the server environment.

The optional third parameter allows you to send a specific HTTP Response Code - this could be used for example to create 301 redirects for search engine purposes. The default Response Code is 302. The third parameter is *only* available with **location** redirects, and not *refresh*. Examples:

```
if ($logged_in == FALSE)
{
    redirect('/login/form/');
}

// with 301 redirect
redirect('/article/13', 'location', 301);
```

: In order for this function to work it must be used before anything is outputted to the browser since it utilizes server headers.

: For very fine grained control over headers, you should use the *Output Library* </libraries/output> `set_header()` method.

: To IIS users: if you hide the *Server* HTTP header, the *auto* method won't detect IIS, in that case it is advised you explicitly use the **refresh** method.

: When the **location** method is used, an HTTP status code of 303 will *automatically* be selected when the page is currently accessed via POST and HTTP/1.1 is used.

: This function will terminate script execution.

9.1.21 XML Helper

The XML Helper file contains functions that assist in working with XML data.

Page Contents

- XML Helper
 - Loading this Helper
 - `xml_convert()`

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('xml');
```

The following functions are available:

`xml_convert()`

Takes a string as input and converts the following reserved XML characters to entities:

- Ampersands: `&`
- Less than and greater than characters: `<` `>`
- Single and double quotes: `'` `"`
- Dashes: `-`

This function ignores ampersands if they are part of existing character entities. Example

```
$string = xml_convert($string);
```

10.1 Contributing to CodeIgniter

CodeIgniter is a community driven project and accepts contributions of code and documentation from the community. These contributions are made in the form of Issues or [Pull Requests](#) on the [EllisLab CodeIgniter repository](#) on GitHub.

Issues are a quick way to point out a bug. If you find a bug or documentation error in CodeIgniter then please check a few things first:

- There is not already an open Issue
- The issue has already been fixed (check the develop branch, or look for closed Issues)
- Is it something really obvious that you fix it yourself?

Reporting issues is helpful but an even better approach is to send a Pull Request, which is done by “Forking” the main repository and committing to your own copy. This will require you to use the version control system called Git.

10.1.1 Guidelines

Before we look into how, here are the guidelines. If your Pull Requests fail to pass these guidelines it will be declined and you will need to re-submit when you’ve made the changes. This might sound a bit tough, but it is required for us to maintain quality of the code-base.

PHP Style

All code must meet the [Style Guide](#), which is essentially the [Allman indent style](#), underscores and readable operators. This makes certain that all code is the same format as the existing code and means it will be as readable as possible.

Documentation

If you change anything that requires a change to documentation then you will need to add it. New classes, methods, parameters, changing default values, etc are all things that will require a change to documentation. The change-log must also be updated for every change. Also PHPDoc blocks must be maintained.

Compatibility

CodeIgniter is compatible with PHP 5.2.4 so all code supplied must stick to this requirement. If PHP 5.3 or 5.4 functions or features are used then there must be a fallback for PHP 5.2.4.

Branching

CodeIgniter uses the [Git-Flow](#) branching model which requires all pull requests to be sent to the “develop” branch. This is where the next planned version will be developed. The “master” branch will always contain the latest stable version and is kept clean so a “hotfix” (e.g: an emergency security patch) can be applied to master to create a new version, without worrying about other features holding it up. For this reason all commits need to be made to “develop” and any sent to “master” will be closed automatically. If you have multiple changes to submit, please place all changes into their own branch on your fork.

One thing at a time: A pull request should only contain one change. That does not mean only one commit, but one change - however many commits it took. The reason for this is that if you change X and Y but send a pull request for both at the same time, we might really want X but disagree with Y, meaning we cannot merge the request. Using the Git-Flow branching model you can create new branches for both of these features and send two requests.

Signing

You must sign your work, certifying that you either wrote the work or otherwise have the right to pass it on to an open source project. git makes this trivial as you merely have to use `--signoff` on your commits to your CodeIgniter fork.

```
git commit --signoff
```

or simply

```
git commit -s
```

This will sign your commits with the information setup in your git config, e.g.

Signed-off-by: John Q Public <john.public@example.com>

If you are using Tower there is a “Sign-Off” checkbox in the commit window. You could even alias git commit to use the -s flag so you don’t have to think about it.

By signing your work in this manner, you certify to a “Developer’s Certificate of Origin”. The current version of this certificate is in the *Developer’s Certificate of Origin 1.1* file in the root of this documentation.

10.2 Developer’s Certificate of Origin 1.1

By making a contribution to this project, I certify that:

1. The contribution was created in whole or in part by me and I have the right to submit it under the open source license indicated in the file; or
2. The contribution is based upon previous work that, to the best of my knowledge, is covered under an appropriate open source license and I have the right under that license to submit that work with modifications, whether created in whole or in part by me, under the same open source license (unless I am permitted to submit under a different license), as indicated in the file; or
3. The contribution was provided directly to me by some other person who certified (1), (2) or (3) and I have not modified it.
4. I understand and agree that this project and the contribution are public and that a record of the contribution (including all personal information I submit with it, including my sign-off) is maintained indefinitely and may be redistributed consistent with this project or the open source license(s) involved.

10.3 Developer's Certificate of Origin 1.1

By making a contribution to this project, I certify that:

1. The contribution was created in whole or in part by me and I have the right to submit it under the open source license indicated in the file; or
2. The contribution is based upon previous work that, to the best of my knowledge, is covered under an appropriate open source license and I have the right under that license to submit that work with modifications, whether created in whole or in part by me, under the same open source license (unless I am permitted to submit under a different license), as indicated in the file; or
3. The contribution was provided directly to me by some other person who certified (1), (2) or (3) and I have not modified it.
4. I understand and agree that this project and the contribution are public and that a record of the contribution (including all personal information I submit with it, including my sign-off) is maintained indefinitely and may be redistributed consistent with this project or the open source license(s) involved.

10.5 Change Log

10.5.1 Version 3.0 (planned)

Release Date: Not Released

- License
 - CodeIgniter has been relicensed with the Open Software License (3.0), eliminating its old proprietary licensing.
 - * All system files are licensed with OSL 3.0.
 - * Config, error, and sample files shipped in the application folder are licensed with the Academic Free License (3.0) to allow you to retain all licensing authority over your own application code.
- General Changes
 - PHP 5.1.6 is no longer supported. CodeIgniter now requires PHP 5.2.4.
 - Changed filenames convention (class file names now must be Ucfirst and everything else in lowercase).
 - `$_SERVER['CI_ENV']` can now be set to control the `ENVIRONMENT` constant.
 - Added an optional backtrace to php-error template.
 - Added Android to the list of user agents.
 - Added Windows 7, Windows 8, Android, Blackberry, iOS and PlayStation 3 to the list of user platforms.
 - Added Fennec (Firefox for mobile) to the list of mobile user agents.
 - Ability to log certain error types, not all under a threshold.
 - Added support for pem, p10, p12, p7a, p7c, p7m, p7r, p7s, crt, crl, der, kdb, rsa, cer, sst, csr Certs to mimes.php.
 - Added support for pgp, gpg, zsh and cdr files to mimes.php.
 - Added support for 3gp, 3g2, mp4, wmv, f4v, vlc Video files to mimes.php.
 - Added support for m4a, aac, m4u, xspf, au, ac3, flac, ogg, wma Audio files to mimes.php.
 - Added support for kmz and kml (Google Earth) files to mimes.php.
 - Added support for ics Calendar files to mimes.php.
 - Added support for rar, jar and 7zip archives to mimes.php.
 - Updated support for xml (‘application/xml’) and xsl (‘application/xml’, ‘text/xsl’) files in mimes.php.

- Updated support for doc files in `mimes.php`.
- Updated support for docx files in `mimes.php`.
- Updated support for php files in `mimes.php`.
- Updated support for zip files in `mimes.php`.
- Updated support for csv files in `mimes.php`.
- Added Romanian, Greek, Vietnamese and Cyrillic characters in `application/config/foreign_characters.php`.
- Changed logger to only `chmod` when file is first created.
- Removed previously deprecated SHA1 Library.
- Removed previously deprecated use of `$autoload['core']` in `application/config/autoload.php`. Only entries in `$autoload['libraries']` are auto-loaded now.
- Removed previously deprecated EXT constant.
- Updated all classes to be written in PHP 5 style, with visibility declarations and no `var` usage for properties.
- Moved error templates to `application/views/errors/`.
- Moved the Log class to `application/core/`
- Global config files are loaded first, then environment ones. Environment config keys overwrite base ones, allowing to only set the keys we want changed per environment.
- Changed detection of `$view_folder` so that if it's not found in the current path, it will now also be searched for under the application folder.
- Path constants `BASEPATH`, `APPPATH` and `VIEWPATH` are now (internally) defined as absolute paths.
- Updated email validation methods to use `filter_var()` instead of PCRE.
- Changed environment defaults to report all errors in *development* and only fatal ones in *testing*, *production* but only display them in *development*.
- Updated `ip_address` database field lengths from 16 to 45 for supporting IPv6 address on *Trackback Library* and *Captcha Helper*.
- Removed *cheatsheets* and *quick_reference* PDFs from the documentation.
- Added support non-HTML error templates for CLI applications.
- Added availability checks where usage of dangerous functions like `eval()` and `exec()` is required.
- Added support for changing the file extension of log files using `$config['log_file_extension']`.

- **Helpers**

- *Date Helper* changes include:
 - * `now()` now works with all timezone strings supported by PHP.
 - * Added an optional third parameter to `timespan()` that constrains the number of time units displayed.
 - * Added an optional parameter to `timezone_menu()` that allows more attributes to be added to the generated select tag.
 - * Deprecated `standard_date()`, which now just uses the native `date()` with [DateTime constants](#).
 - * Added function `date_range()` that generates a list of dates between a specified period.

- *URL Helper* changes include:
 - * Deprecated *separator* options **dash** and **underscore** for function `url_title()` (they are only aliases for `'-'` and `'_'` respectively).
 - * `url_title()` will now trim extra dashes from beginning and end.
 - * `anchor_popup()` will now fill the *href* attribute with the URL and its JS code will return FALSE instead.
 - * Added JS window name support to the `anchor_popup()` function.
 - * Added support (auto-detection) for HTTP/1.1 response code 303 in `redirect()`.
 - * Changed `redirect()` to choose the **refresh** method only on IIS servers, instead of all servers on Windows (when **auto** is used).
 - * Changed `anchor()`, `anchor_popup()`, and `redirect()` to support protocol-relative URLs (e.g. `//ellislab.com/codeigniter`).
- *HTML Helper* changes include:
 - * Added more doctypes.
 - * Changed application and environment config files to be loaded in a cascade-like manner.
 - * The doctypes array is now cached and loaded only once.
- *Inflector Helper* changes include:
 - * Changed `humanize()` to allow passing an input separator as its second parameter.
 - * Refactored `plural()` and `singular()` to avoid double pluralization and support more words.
- *Download Helper* changes include:
 - * Added an optional third parameter to `force_download()` that enables/disables sending the actual file MIME type in the Content-Type header (disabled by default).
 - * Added a work-around in `force_download()` for a bug Android <= 2.1, where the filename extension needs to be in uppercase.
 - * Added support for reading from an existing file path by passing NULL as the second parameter to `force_download()` (useful for large files and/or safely transmitting binary data).
- *Form Helper* changes include:
 - * `form_dropdown()` will now also take an array for unity with other form helpers.
 - * `form_prep()`'s second argument now only accepts a boolean value, which determines whether the value is escaped for a `<textarea>` or a regular `<input>` element.
- *Security Helper* changes include:
 - * `do_hash()` now uses PHP's native `hash()` function (supporting more algorithms) and is deprecated.
 - * `strip_image_tags()` is now an alias for the same method in the *Security Library*.
- *Smiley Helper* changes include:
 - * Removed previously deprecated function `js_insert_smiley()`.
 - * Changed application and environment config files to be loaded in a cascade-like manner.
 - * The smileys array is now cached and loaded only once.
- *File Helper* changes include:

- * `set_realpath()` can now also handle file paths as opposed to just directories.
- * Added an optional parameter to `delete_files()` to enable it to skip deleting files such as *.htaccess* and *index.html*.
- * Deprecated function `read_file()` - it's just an alias for PHP's native `file_get_contents()`.
- *String Helper* changes include:
 - * Deprecated function `repeater()` - it's just an alias for PHP's native `str_repeat()`.
 - * Deprecated function `trim_slashes()` - it's just an alias for PHP's native `trim()` (with a slash as its second argument).
 - * Deprecated randomization type options **unique** and **encrypt** for function `random_string()` (they are only aliases for **md5** and **sha1** respectively).
- *CAPTCHA Helper* changes include:
 - * Added *word_length* and *pool* options to allow customization of the generated word.
 - * Added *colors* configuration to allow customization for the *background*, *border*, *text* and *grid* colors.
 - * Added *filename* to the returned array elements.
- *Directory Helper* `directory_map()` will now append `DIRECTORY_SEPARATOR` to directory names in the returned array.
- *Array Helper* `element()` and `elements()` now return `NULL` instead of `FALSE` when the required elements don't exist.
- *Language Helper* `lang()` now accepts an optional list of additional HTML attributes.
- Deprecated the *Email Helper* as its `valid_email()`, `send_email()` functions are now only aliases for PHP native functions `filter_var()` and `mail()` respectively.
- Database
 - Added **dsn** configuration setting for drivers that support DSN strings (PDO, PostgreSQL, Oracle, ODBC, CUBRID).
 - Added **schema** configuration setting (defaults to *public*) for drivers that might need it (currently used by PostgreSQL and ODBC).
 - Added subdrivers support (currently only used by PDO).
 - Added an optional database name parameter to `db_select()`.
 - Removed `protect_identifiers()` and renamed internal method `_protect_identifiers()` to it instead - it was just an alias.
 - Renamed internal method `_escape_identifiers()` to `escape_identifiers()`.
 - Updated `escape_identifiers()` to accept an array of fields as well as strings.
 - MySQL and MySQLi drivers now require at least MySQL version 5.1.
 - `db_set_charset()` now only requires one parameter (collation was only needed due to legacy support for MySQL versions prior to 5.1).
 - `db_select()` will now always (if required by the driver) be called by `db_connect()` / `db_pconnect()` instead of only when initializing.
 - Replaced the `_error_message()` and `_error_number()` methods with `error()`, which returns an array containing the last database error code and message.

- Improved `version()` implementation so that drivers that have a native function to get the version number don't have to be defined in the core `DB_driver` class.
- Added capability for packages to hold *config/database.php* config files.
- Added MySQL client compression support.
- Added encrypted connections support (for *mysql*, *sqlsrv* and PDO with *sqlsrv*).
- Removed *Loader Class* from Database error tracing to better find the likely culprit.
- Added support for SQLite3 database driver.
- Added Interbase/Firebird database support via the *ibase* driver.
- Added ODBC support for `create_database()`, `drop_database()` and `drop_table()` in *Database Forge*.
- *Query Builder* changes include:
 - * Renamed the Active Record class to Query Builder to remove confusion with the Active Record design pattern.
 - * Added the ability to insert objects with `insert_batch()`.
 - * Added new methods that return the SQL string of queries without executing them: `get_compiled_select()`, `get_compiled_insert()`, `get_compiled_update()`, `get_compiled_delete()`.
 - * Added an optional parameter that allows to disable escaping (useful for custom fields) for methods `join()`, `order_by()`, `where_in()`, `or_where_in()`, `where_not_in()`, `or_where_not_in()`, `insert()`, `insert_batch()`.
 - * Added support for `join()` with multiple conditions.
 - * Added support for *USING* in `join()`.
 - * Added seed values support for random ordering with `order_by(seed, 'RANDOM')`.
 - * Changed `limit()` to ignore NULL values instead of always casting to integer.
 - * Changed `offset()` to ignore empty values instead of always casting to integer.
 - * Methods `insert_batch()` and `update_batch()` now return an integer representing the number of rows affected by them.
- *Database Results* changes include:
 - * Added a constructor to the `DB_result` class and moved all driver-specific properties and logic out of the base `DB_driver` class to allow better abstraction.
 - * Added method `unbuffered_row()` for fetching a row without prefetching the whole result (consume less memory).
 - * Renamed former method `_data_seek()` to `data_seek()` and made it public.
- Improved support for the MySQLi driver, including:
 - * OOP style of the PHP extension is now used, instead of the procedural aliases.
 - * Server version checking is now done via `mysqli::$server_info` instead of running an SQL query.
 - * Added persistent connections support for PHP >= 5.3.
 - * Added support for `backup()` in *Database Utilities*.

- * Changed methods `trans_begin()`, `trans_commit()` and `trans_rollback()` to use the PHP API instead of sending queries.
- Improved support of the PDO driver, including:
 - * Added support for `create_database()`, `drop_database()` and `drop_table()` in *Database Forge*.
 - * Added support for `list_fields()` in *Database Results*.
 - * Subdrivers are now isolated from each other instead of being in one large class.
- Improved support of the PostgreSQL driver, including:
 - * `pg_version()` is now used to get the database version number, when possible.
 - * Added `db_set_charset()` support.
 - * Added support for `optimize_table()` in *Database Utilities* (rebuilds table indexes).
 - * Added boolean data type support in `escape()`.
 - * Added `update_batch()` support.
 - * Removed `limit()` and `order_by()` support for *UPDATE* and *DELETE* queries as PostgreSQL does not support those features.
 - * Added a work-around for dead persistent connections to be re-created after a database restart.
 - * Changed `db_connect()` to include the (new) **schema** value into Postgre's **search_path** session variable.
 - * `pg_escape_literal()` is now used for escaping strings, if available.
- Improved support of the CUBRID driver, including:
 - * Added DSN string support.
 - * Added persistent connections support.
 - * Improved `list_databases()` in *Database Utility* (until now only the currently used database was returned).
- Improved support of the MSSQL and SQLSRV drivers, including:
 - * Added random ordering support.
 - * Added support for `optimize_table()` in *Database Utility*.
 - * Added escaping with *QUOTE_IDENTIFIER* setting detection.
 - * Added port handling support for UNIX-based systems (MSSQL driver).
 - * Added *OFFSET* support for SQL Server 2005 and above.
 - * Added `db_set_charset()` support (MSSQL driver).
- Improved support of the Oracle (OCI8) driver, including:
 - * Added DSN string support (Easy Connect and TNS).
 - * Added support for `drop_table()` in *Database Forge*.
 - * Added support for `list_databases()` in *Database Utilities*.
 - * Generally improved for speed and cleaned up all of its components.
 - * `num_rows()` is now only called explicitly by the developer and no longer re-executes statements.
- Improved support of the SQLite driver, including:

- * Added support for `replace()` in *Query Builder*.
- * Added support for `drop_table()` in *Database Forge*.
- *Database Forge* changes include:
 - * Added an optional second parameter to `drop_table()` that allows adding the **IF EXISTS** condition, which is no longer the default.
 - * Added support for passing a custom database object to the loader.
 - * Deprecate `add_column()`'s third method. *AFTER* clause should now be added to the field definition array instead.
 - * Added support for usage of the *FIRST* clause in `add_column()` for MySQL and CUBRID.
 - * Overall improved support for all of the drivers.
- *Database Utility* changes include:
 - * Added support for passing a custom database object to the loader.
 - * Modified the class to no longer extend *Database Forge*, which has been a deprecated behavior for awhile.
 - * Overall improved support for all of the drivers.
 - * Added *foreign_key_checks* option to MySQL/MySQLi backup, allowing statement to disable/re-enable foreign key checks to be inserted into the backup output.
- Libraries
 - *Session Library* changes include:
 - * Library changed to *Driver* with classic Cookie driver as default.
 - * Added Native PHP Session driver to work with `$_SESSION`.
 - * Custom drivers can be added anywhere in package paths and be loaded with the library.
 - * Drivers interchangeable on the fly.
 - * New **tempdata** feature allows setting user data items with an expiration time.
 - * Added `default $config['sess_driver']` and `$config['sess_valid_drivers']` items to *config.php* file.
 - * Cookie driver now respects *php.ini*'s *session.gc_probability* and *session.gc_divisor* settings.
 - * Cookie driver now uses HMAC authentication instead of the simple md5 checksum.
 - * The Cookie driver now also checks authentication on encrypted session data.
 - * Changed the Cookie driver to select only one row when using database sessions.
 - * Cookie driver now only writes to database at end of request when using database.
 - * Cookie driver now uses PHP functions for faster array manipulation when using database.
 - * Added `all_flashdata()` method to session class. Returns an associative array of only flashdata.
 - * Added `has_userdata()` method to verify existence of userdata item.
 - * Added `tempdata()`, `set_tempdata()`, and `unset_tempdata()` methods for manipulating tempdata.
 - * `keep_flashdata()` now accepts an array of keys.
 - * Added *debug* level log messages for key events in the session validation process.

- *File Uploading Library* changes include:
 - * Added **max_filename_increment** config setting.
 - * Added an **index** parameter to the `data()` method.
 - * Added the **min_width** and **min_height** options for images.
 - * Removed method `clean_file_name()` and its usage in favor of *Security Library*'s `sanitize_filename()`.
 - * Added **file_ext_tolower** config setting.
 - * Added **mod_mime_fix** option to disable suffixing multiple file extensions with an underscore.
- *Cart library* changes include:
 - * `insert()` now auto-increments quantity for an item when inserted twice instead of resetting it, this is the default behaviour of large e-commerce sites.
 - * *Product Name* strictness can be disabled by switching the `$product_name_safe` property to `FALSE`.
 - * Added method `remove()` to remove a cart item, updating with quantity of 0 seemed like a hack but has remained to retain compatibility.
 - * Added method `get_item()` to enable retrieving data for a single cart item.
 - * Added unicode support for product names.
- *Image Manipulation library* changes include:
 - * The `initialize()` method now only sets existing class properties.
 - * Added support for 3-length hex color values for `wm_font_color` and `wm_shadow_color` properties, as well as validation for them.
 - * Class properties `wm_font_color`, `wm_shadow_color` and `wm_use_drop_shadow` are now protected, to avoid breaking the `text_watermark()` method if they are set manually after initialization.
 - * If property `maintain_ratio` is set to `TRUE`, `image_reproportion()` now doesn't need both width and height to be specified.
 - * Property `maintain_ratio` is now taken into account when resizing images using ImageMagick library.
 - * Added support for maintaining transparency for PNG images in method `text_watermark()`.
- *Form Validation library* changes include:
 - * Added method `error_array()` to return all error messages as an array.
 - * Added method `set_data()` to set an alternative data array to be validated instead of the default `$_POST`.
 - * Added method `reset_validation()` which resets internal validation variables in case of multiple validation routines.
 - * Added support for setting error delimiters in the config file via `$config['error_prefix']` and `$config['error_suffix']`.
 - * Internal method `_execute()` now considers input data to be invalid if a specified rule is not found.
 - * Removed method `is_numeric()` as it exists as a native PHP function and `_execute()` will find and use that (the **is_numeric** rule itself is deprecated since 1.6.1).
 - * Native PHP functions used as rules can now accept an additional parameter, other than the data itself.
 - * Updated method `set_rules()` to accept an array of rules as well as a string.

- * Fields that have empty rules set no longer run through validation (and therefore are not considered erroneous).
- * Added rule **differs** to check if the value of a field differs from the value of another field.
- * Added rule **valid_url**.
- * Added support for named parameters in error messages.
- * *Language* line keys must now be prefixed with **form_validation_**.
- * Added rule **alpha_numeric_spaces**.
- *Caching Library* changes include:
 - * Added Wincache driver.
 - * Added Redis driver.
 - * Added a *key_prefix* option for cache IDs.
 - * Updated driver `is_supported()` methods to log at the “debug” level.
- *Email library* changes include:
 - * Added custom filename to `Email::attach()` as `$this->email->attach($filename, $disposition, $newname)`.
 - * Added possibility to send attachment as buffer string in `Email::attach()` as `$this->email->attach($buffer, $disposition, $newname, $mime)`.
 - * Added dsn (delivery status notification) option.
 - * Renamed method `_set_header()` to `set_header()` and made it public to enable adding custom headers in the *Email Library*.
 - * Successfully sent emails will automatically clear the parameters.
 - * Added a *return_path* parameter to the `from()` method.
 - * Removed the second parameter (character limit) from internal method `_prep_quoted_printable()` as it is never used.
 - * Internal method `_prep_quoted_printable()` will now utilize the native `quoted_printable_encode()`, `imap_8bit()` functions (if available) when CRLF is set to “rn”.
 - * Default charset now relies on the global `$config['charset']` setting.
 - * Removed unused protected method `_get_ip()` (*Input Library*’s `ip_address()` should be used anyway).
 - * Internal method `_prep_q_encoding()` now utilizes PHP’s *mbstring* and *iconv* extensions (when available) and no longer has a second (`$from`) argument.
 - * Added an optional parameter to `print_debugger()` to allow specifying which parts of the message should be printed (‘headers’, ‘subject’, ‘body’).
 - * Added SMTP keepalive option to avoid opening the connection for each `Email::send()`. Accessible as `$smtp_keepalive`.
 - * Public method `set_header()` now filters the input by removing all “\r” and “\n” characters.
- *Pagination Library* changes include:
 - * Added support for the anchor “rel” attribute.
 - * Added support for setting custom attributes.

- * Deprecated usage of the “anchor_class” setting (use the new “attributes” setting instead).
- * Added `$config['reuse_query_string']` to allow automatic repopulation of query string arguments, combined with normal URI segments.
- * Removed the default ` ` from a number of the configuration variables.
- * Added the ability to use a proxy with the *XML-RPC Library*.
- *Encryption Library* changes include:
 - * Added support for hashing algorithms other than SHA1 and MD5.
 - * Removed previously deprecated `sha1()` method.
- *Profiler Library* changes include:
 - * Database object names are now being displayed.
 - * The sum of all queries running times in seconds is now being displayed.
 - * Added support for displaying the HTTP DNT (“Do Not Track”) header.
 - * Added support for displaying `$_FILES`.
- *Migration Library* changes include:
 - * Added support for timestamp-based migrations (enabled by default).
 - * Added `$config['migration_type']` to allow switching between *sequential* and *timestamp* migrations.
- *User Agent Library* will now check if robots are pretending to be mobile clients (helps with e.g. Google indexing mobile website versions).
- Added support for setting *Table* class defaults in a config file.
- Core
 - *URI Library* changes include:
 - * Changed private methods to protected so that MY_URI can override them.
 - * Renamed internal method `_parse_cli_args()` to `_parse_argv()`.
 - * Renamed internal method `_detect_uri()` to `_parse_request_uri()`.
 - * Changed `_parse_request_uri()` to accept absolute URIs for compatibility with HTTP/1.1 as per *RFC2616* <<http://www.ietf.org/rfc/rfc2616.txt>>.
 - * Added protected method `_parse_query_string()` to URI paths in the the **QUERY_STRING** value, like `_parse_request_uri()` does.
 - * Changed `_fetch_uri_string()` to try the **PATH_INFO** variable first when auto-detecting.
 - *Loader Library* changes include:
 - * Added method `get_vars()` to the Loader to retrieve all variables loaded with `$this->load->vars()`.
 - * `_ci_autoloader()` is now a protected method.
 - * Added autoloading of drivers with `$autoload['drivers']`.
 - * `$config['rewrite_short_tags']` now has no effect when using PHP 5.4 as `<?=>` will always be available.
 - * Changed method `config()` to return whatever `CI_Config::load()` returns instead of always being void.

- * Added support for model aliasing on autoload.
- * Changed method `is_loaded()` to ask for the (case sensitive) library name instead of its instance name.
- * Removed `$_base_classes` property and unified all class data in `$_ci_classes` instead.
- * Added method `clear_vars()` to allow clearing the cached variables for views.
- *Input Library* changes include:
 - * Added method `()` to retrieve `$_SERVER['REQUEST_METHOD']`.
 - * Added support for arrays and network addresses (e.g. 192.168.1.1/24) for use with the *proxy_ips* setting.
 - * Added method `input_stream()` to aid in using **php://input** stream data such as one passed via PUT, DELETE and PATCH requests.
 - * Changed method `valid_ip()` to use PHP's native `filter_var()` function.
 - * Changed internal method `_sanitize_globals()` to skip enforcing reversal of *register_globals* in PHP 5.4+, where this functionality no longer exists.
 - * Changed methods `get()`, `post()`, `get_post()`, `cookie()`, `server()`, `user_agent()` to return NULL instead of FALSE when no value is found.
 - * Added method `post_get()` and changed `get_post()` to search in GET data first. Both methods' names now properly match their GET/POST data search priorities.
 - * Changed method `_fetch_from_array()` to parse array notation in field name.
 - * Added an option for `_clean_input_keys()` to return FALSE instead of terminating the whole script.
 - * Deprecated the `is_cli_request()` method, it is now an alias for the new `is_cli()` common function.
- *Common functions* changes include:
 - * Added function `get_mimes()` to return the *application/config/mimes.php* array.
 - * Added support for HTTP code 303 ("See Other") in `set_status_header()`.
 - * Removed redundant conditional to determine HTTP server protocol in `set_status_header()`.
 - * Changed `_exception_handler()` to respect *php.ini display_errors* setting.
 - * Added function `is_https()` to check if a secure connection is used.
 - * Added function `is_cli()` to replace the `CI_Input::is_cli_request()` method.
 - * Added function `function_usable()` to check if a function exists and is not disabled by *Suhosin* <<http://www.hardened-php.net/suhosin/>>.
 - * Removed the third (*\$php_error*) from function `log_message()`.
- *Output Library* changes include:
 - * Added a second argument to method `set_content_type()` that allows setting the document charset as well.
 - * Added methods `get_content_type()` and `get_header()`.
 - * Added method `delete_cache()`.
- *Config Library* changes include:

- * Changed `site_url()` method to accept an array as well.
- * Removed internal method `_assign_to_config()` and moved its implementation to *CodeIgniter.php* instead.
- * `item()` now returns NULL instead of FALSE when the required config item doesn't exist.
- * Added an optional second parameter to both `base_url()` and `site_url()` that allows enforcing of a protocol different than the one in the *base_url* configuration setting.
- *Security Library* changes include:
 - * Added method `strip_image_tags()`.
 - * Added `$config['csrf_regeneration']`, which makes token regeneration optional.
 - * Added `$config['csrf_exclude_uris']`, which allows you list URIs which will not have the CSRF validation methods run.
 - * Modified method `sanitize_filename()` to read a public `$filename_bad_chars` property for getting the invalid characters list.
- *URI Routing* changes include:
 - * Added possibility to route requests using HTTP verbs.
 - * Added possibility to route requests using callbacks.
 - * Added a new reserved route (*translate_uri_dashes*) to allow usage of dashes in the controller and method URI segments.
 - * Deprecated methods `fetch_directory()`, `fetch_class()` and `fetch_method()` in favor of their respective public properties.
- *Language Library* changes include:
 - * Changed method `load()` to filter the language name with `ctype_digit()`.
 - * Added an optional second parameter to method `line()` to disable error login for line keys that were not found.
 - * Language files are now loaded in a cascading style with the one in **system/** always loaded and overridden afterwards, if another one is found.
- Removed `CI_CORE` boolean constant from *CodeIgniter.php* (no longer Reactor and Core versions).
- Log Library will now try to create the **log_path** directory if it doesn't exist.
- Added support for HTTP-Only cookies with new config option *cookie_httponly* (default FALSE).
- Renamed method `_call_hook()` to `call_hook()` in the *Hooks Library*.
- `$config['time_reference']` now supports all timezone strings supported by PHP.
- Fatal PHP errors are now also passed to `_exception_handler()`, so they can be logged.

Bug fixes for 3.0

- Fixed a bug where `unlink()` raised an error if cache file did not exist when you try to delete it.
- Fixed a bug (#181) where a mis-spelling was in the form validation language file.
- Fixed a bug (#159, #163) - *Query Builder* nested transactions didn't work properly due to `_trans_depth` not being incremented.
- Fixed a bug (#737, #75) - *Pagination* anchor class was not set properly when using initialize method.

- Fixed a bug (#419) - `auto_link()` didn't recognize URLs that come after a word boundary.
- Fixed a bug (#724) - *Form Validation Library* rule **is_unique** didn't check if a database connection exists.
- Fixed a bug (#647) - *Zip Library* internal method `_get_mod_time()` didn't suppress possible "stat failed" errors generated by `filemtime()`.
- Fixed a bug (#157, #174) - *Image Manipulation Library* method `clear()` didn't completely clear properties.
- Fixed a bug where *Database Forge* method `create_table()` with PostgreSQL database could lead to fetching the whole table.
- Fixed a bug (#795) - *Form Helper* `form_open()` didn't add the default form *method* and *accept-charset* when an empty array is passed to it.
- Fixed a bug (#797) - `timespan()` was using incorrect seconds for year and month.
- Fixed a bug in `CI_Cart::contents()` where if called without a `TRUE` (or `equal`) parameter, it would fail due to a typo.
- Fixed a bug (#696) - make `oci_execute()` calls inside `num_rows()` non-committing, since they are only there to reset which row is next in line for `oci_fetch` calls and thus don't need to be committed.
- Fixed a bug (#406) - *SQLSRV DB driver* not returning resource on `db_pconnect()`.
- Fixed a bug in `CI_Image_lib::gd_loaded()` where it was possible for the script execution to end or a PHP `E_WARNING` message to be emitted.
- Fixed a bug in the *Pagination library* where when `use_page_numbers=TRUE` previous link and page 1 link did not have the same url.
- Fixed a bug (#561) - Errors in *XML-RPC Library* were not properly escaped.
- Fixed a bug (#904) - `CI_Loader::initialize()` caused a PHP Fatal error to be triggered if error level `E_STRICT` is used.
- Fixed a hosting edge case where an empty `$_SERVER['HTTPS']` variable would evaluate to 'on'.
- Fixed a bug (#154) - `CI_Session::sess_update()` caused the session to be destroyed on pages where multiple AJAX requests were executed at once.
- Fixed a possible bug in `CI_Input::is_ajax_request()` where some clients might not send the `X-Requested-With` HTTP header value exactly as 'XmlHttpRequest'.
- Fixed a bug (#1039) - MySQL's `_backup()` method failed due to a table name not being escaped.
- Fixed a bug (#1070) - `CI_DB_driver::initialize()` didn't set a character set if a database is not selected.
- Fixed a bug (#177) - `CI_Form_validation::set_value()` didn't set the default value if POST data is `NULL`.
- Fixed a bug (#68, #414) - Oracle's `escape_str()` didn't properly escape LIKE wild characters.
- Fixed a bug (#81) - ODBC's `list_fields()` and `field_data()` methods skipped the first column due to `odbc_field_*()` functions' index starting at 1 instead of 0.
- Fixed a bug (#129) - ODBC's `num_rows()` returned -1 in some cases, due to not all subdrivers supporting the `odbc_num_rows()` function.
- Fixed a bug (#153) - `E_NOTICE` being generated by `getimagesize()` in the *File Uploading Library*.
- Fixed a bug (#611) - *SQLSRV*'s error handling methods used to issue warnings when there's no actual error.
- Fixed a bug (#1036) - `is_write_type()` method in the *Database Library* didn't return `TRUE` for `RENAME` queries.
- Fixed a bug in PDO's `_version()` method where it used to return the client version as opposed to the server one.

- Fixed a bug in PDO's `insert_id()` method where it could've failed if it's used with Postgre versions prior to 8.1.
- Fixed a bug in CUBRID's `affected_rows()` method where a connection resource was passed to `cubrid_affected_rows()` instead of a result.
- Fixed a bug (#638) - `db_set_charset()` ignored its arguments and always used the configured charset instead.
- Fixed a bug (#413) - Oracle's error handling methods used to only return connection-related errors.
- Fixed a bug (#1101) - MySQL/MySQLi result method `field_data()` was implemented as if it was handling a DESCRIBE result instead of the actual result set.
- Fixed a bug in Oracle's *Database Forge Class* method `_create_table()` where it failed with AUTO_INCREMENT as it's not supported.
- Fixed a bug (#1080) - When using the SMTP protocol, the *Email Library* `send()` method was returning TRUE even if the connection/authentication against the server failed.
- Fixed a bug (#306) - ODBC's `insert_id()` method was calling non-existent function `odbc_insert_id()`, which resulted in a fatal error.
- Fixed a bug in Oracle's DB_result class where the cursor id passed to it was always NULL.
- Fixed a bug (#64) - Regular expression in `DB_query_builder.php` failed to handle queries containing SQL bracket delimiters in the join condition.
- Fixed a bug in the *Session Library* where a PHP E_NOTICE error was triggered by `_unserialize()` due to results from databases such as MSSQL and Oracle being space-padded on the right.
- Fixed a bug (#501) - `set_rules()` to check if the request method is not 'POST' before aborting, instead of depending on `count($_POST)` in the *Form Validation Library*.
- Fixed a bug (#136) - PostgreSQL, MySQL and MySQLi's `escape_str()` method didn't properly escape LIKE wild characters.
- Fixed a bug in the library loader where some PHP versions wouldn't execute the class constructor.
- Fixed a bug (#88) - An unexisting property was used for configuration of the Memcache cache driver.
- Fixed a bug (#14) - `create_database()` method in the *Database Forge Library* didn't utilize the configured database character set.
- Fixed a bug (#23, #1238) - `delete_all()` in the *Database Caching Library* <database/caching> used to delete .htaccess and index.html files, which is a potential security risk.
- Fixed a bug in *Trackback Library* method `validate_url()` where it didn't actually do anything, due to input not being passed by reference.
- Fixed a bug (#11, #183, #863) - `CI_Form_validation::_execute()` silently continued to the next rule, if a rule method/function is not found.
- Fixed a bug (#122) - routed URI string was being reported incorrectly in sub-directories.
- Fixed a bug (#1242) - `read_dir()` in the *Zip Library* wasn't compatible with Windows.
- Fixed a bug (#306) - ODBC driver didn't have an `_insert_batch()` method, which resulted in fatal error being triggered when `insert_batch()` is used with it.
- Fixed a bug in MSSQL and SQLSrv's `_truncate()` where the TABLE keyword was missing.
- Fixed a bug in PDO's `trans_commit()` method where it failed due to an erroneous property name.
- Fixed a bug (#798) - `update()` used to ignore LIKE conditions that were set with `like()`.
- Fixed a bug in Oracle's and MSSQL's `delete()` methods where an erroneous SQL statement was generated when used with `limit()`.

- Fixed a bug in SQLSRV's delete() method where like() and limit() conditions were ignored.
- Fixed a bug (#1265) - Database connections were always closed, regardless of the 'pconnect' option value.
- Fixed a bug (#128) - *Language Library* did not correctly keep track of loaded language files.
- Fixed a bug (#1242) - Added Windows path compatibility to function read_dir of ZIP library.
- Fixed a bug (#1349) - get_extension() in the *File Uploading Library* returned the original filename when it didn't have an actual extension.
- Fixed a bug (#1273) - E_NOTICE being generated by *Query Builder*'s set_update_batch() method.
- Fixed a bug (#44, #110) - *Upload library*'s clean_file_name() method didn't clear '!' and '#' characters.
- Fixed a bug (#121) - CI_DB_result::row() returned an array when there's no actual result to be returned.
- Fixed a bug (#319) - SQLSRV's affected_rows() method failed due to a scrollable cursor being created for write-type queries.
- Fixed a bug (#356) - PostgreSQL driver didn't have an _update_batch() method, which resulted in fatal error being triggered when update_batch() is used with it.
- Fixed a bug (#784, #862) - *Database Forge* method create_table() failed on SQLSRV/MSSQL when used with 'IF NOT EXISTS'.
- Fixed a bug (#1419) - libraries/Driver.php had a static variable that was causing an error.
- Fixed a bug (#1411) - the *Email library* used its own short list of MIMEs instead the one from config/mimes.php.
- Fixed a bug where the magic_quotes_runtime setting wasn't turned off for PHP 5.3 (where it is indeed deprecated, but not non-existent).
- Fixed a bug (#666) - *Output library*'s set_content_type() method didn't set the document charset.
- Fixed a bug (#784, #861) - *Database Forge* method create_table() used to accept constraints for MSSQL/SQLSRV integer-type columns.
- Fixed a bug (#706) - SQLSRV/MSSQL didn't escape field names.
- Fixed a bug (#1452) - protect_identifiers() didn't properly detect identifiers with spaces in their names.
- Fixed a bug where protect_identifiers() ignored its extra arguments when the value passed to it is an array.
- Fixed a bug where _has_operator() didn't detect BETWEEN.
- Fixed a bug in *Query Builder*'s join() method where it failed with identifiers containing dashes.
- Fixed a bug (#1264) - *Database Forge* and *Database Utilities* didn't update/reset the databases and tables list cache when a table or a database is created, dropped or renamed.
- Fixed a bug (#7) - *Query Builder*'s join() method only escaped one set of conditions.
- Fixed a bug (#1321) - Core Exceptions class couldn't find the errors/ folder in some cases.
- Fixed a bug (#1202) - *Encryption Library* encode_from_legacy() didn't set back the encrypt mode on failure.
- Fixed a bug (#145) - compile_binds() failed when the bind marker was present in a literal string within the query.
- Fixed a bug in protect_identifiers() where if passed along with the field names, operators got escaped as well.
- Fixed a bug (#10) - *URI Library* internal method _detect_uri() failed with paths containing a colon.
- Fixed a bug (#1387) - *Query Builder*'s from() method didn't escape table aliases.
- Fixed a bug (#520) - *Date Helper* function nice_date() failed when the optional second parameter is not passed.

- Fixed a bug (#167) - `$config['permitted_uri_chars']` didn't affect URL-encoded characters.
- Fixed a bug (#318) - *Profiling* setting `query_toggle_count` was not settable as described in the manual.
- Fixed a bug (#938) - *Config Library* method `site_url()` added a question mark to the URL string when query strings are enabled even if it already existed.
- Fixed a bug (#999) - *Config Library* method `site_url()` always appended `$config['url_suffix']` to the end of the URL string, regardless of whether a query string exists in it.
- Fixed a bug where *URL Helper* function `anchor_popup()` ignored the `attributes` argument if it is not an array.
- Fixed a bug (#1328) - *Form Validation Library* didn't properly check the type of the form fields before processing them.
- Fixed a bug (#79) - *Form Validation Library* didn't properly validate array fields that use associative keys or have custom indexes.
- Fixed a bug (#427) - *Form Validation Library* method `strip_image_tags()` was an alias to a non-existent method.
- Fixed a bug (#1545) - *Query Builder* method `limit()` wasn't executed properly under Oracle.
- Fixed a bug (#1551) - *Date Helper* function `standard_date()` didn't properly format *W3C* and *ATOM* standard dates.
- Fixed a bug in *Query Builder* method `join()` where literal values were escaped as if they were fields.
- Fixed a bug (#135) - PHP Error logging was impossible without the errors being displayed.
- Fixed a bug (#1613) - *Form Helper* functions `form_multiselect()`, `form_dropdown()` didn't properly handle empty array option groups.
- Fixed a bug (#1605) - *Pagination Library* produced incorrect *previous* and *next* link values.
- Fixed a bug in *SQLSRV's* `affected_rows()` method where an erroneous function name was used.
- Fixed a bug (#1000) - Change syntax of `$view_file` to `$_ci_view_file` to prevent being overwritten by application.
- Fixed a bug (#1757) - *Directory Helper* function `directory_map()` was skipping files and directories named *0*.
- Fixed a bug (#1789) - *Database Library* method `escape_str()` escaped quote characters in *LIKE* conditions twice under MySQL.
- Fixed a bug (#395) - *Unit Testing Library* method `result()` didn't properly check array result columns when called from `report()`.
- Fixed a bug (#1692) - *Database Library* method `display_error()` didn't properly trace the possible error source on Windows systems.
- Fixed a bug (#1745) - `is_write_type()` method in the *Database Library* didn't return *TRUE* for *LOAD* queries.
- Fixed a bug (#1765) - *Database Library* didn't properly detect connection errors for MySQLi.
- Fixed a bug (#1257) - *Query Builder* used to (unnecessarily) group *FROM* clause contents, which breaks certain queries and is invalid for some databases.
- Fixed a bug (#1709) - *Email* headers were broken when using long email subjects and *rn* as *CRLF*.
- Fixed a bug where `MB_ENABLED` was only declared if `UTF8_ENABLED` was set to *TRUE*.
- Fixed a bug where the *Session Library* accepted cookies with *last_activity* values being in the future.

- Fixed a bug (#1897) - *Email Library* triggered PHP E_WARNING errors when *mail* protocol used and `to()` is never called.
- Fixed a bug (#1409) - *Email Library* didn't properly handle multibyte characters when applying Q-encoding to headers.
- Fixed a bug where *Email Library* didn't honor its *wordwrap* setting while handling alternative messages.
- Fixed a bug (#1476, #1909) - *Pagination Library* didn't take into account actual routing when determining the current page.
- Fixed a bug (#1766) - *Query Builder* didn't always take into account the *dbprefix* setting.
- Fixed a bug (#779) - *URI Class* didn't always trim slashes from the *uri_string* as shown in the documentation.
- Fixed a bug (#134) - *Database Caching* method `delete_cache()` didn't work in some cases due to *cachedir* not being initialized properly.
- Fixed a bug (#191) - *Loader Library* ignored attempts for (re)loading databases to `get_instance()->db` even when the old database connection is dead.
- Fixed a bug (#1255) - *User Agent Library* method `is_referral()` only checked if `$_SERVER['HTTP_REFERER']` exists.
- Fixed a bug (#1146) - *Download Helper* function `force_download()` incorrectly sent *Cache-Control* directives *pre-check* and *post-check* to Internet Explorer.
- Fixed a bug (#1811) - *URI Library* didn't properly cache segments for `uri_to_assoc()` and `ruri_to_assoc()`.
- Fixed a bug (#1506) - *Form Helpers* set empty *name* attributes.
- Fixed a bug (#59) - *Query Builder* method `count_all_results()` ignored the DISTINCT clause.
- Fixed a bug (#1624) - *Form Validation Library* rule **matches** didn't properly handle array field names.
- Fixed a bug (#1630) - *Form Helper* function `set_value()` didn't escape HTML entities.
- Fixed a bug (#142) - *Form Helper* function `form_dropdown()` didn't escape HTML entities in option values.
- Fixed a bug (#50) - *Session Library* unnecessarily stripped slashes from serialized data, making it impossible to read objects in a namespace.
- Fixed a bug (#658) - *Routing* wildcard **:any** didn't work as advertised and matched multiple URI segments instead of all characters within a single segment.
- Fixed a bug (#1938) - *Email Library* removed multiple spaces inside a pre-formatted plain text message.
- Fixed a bug (#388, #705) - *URI Library* didn't apply URL-decoding to URI segments that it got from **REQUEST_URI** and/or **QUERY_STRING**.
- Fixed a bug (#122) - *URI Library* method `ruri_string()` didn't include a directory if one is used.
- Fixed a bug - *Routing Library* didn't properly handle *default_controller* in a subdirectory when a method is also specified.
- Fixed a bug (#953) - *post_controller_constructor* hook wasn't called with a *404_override*.
- Fixed a bug (#1220) - *Profiler Library* didn't display information for database objects that are instantiated inside models.
- Fixed a bug (#1978) - *Directory Helper* function `directory_map()`'s return array didn't make a distinction between directories and file indexes when a directory with a numeric name is present.
- Fixed a bug (#777) - *Loader Library* didn't look for helper extensions in added package paths.
- Fixed a bug (#18) - *APC Cache* driver didn't (un)serialize data, resulting in failure to store objects.

- Fixed a bug (#188) - *Unit Testing Library* filled up logs with error messages for non-existing language keys.
- Fixed a bug (#113) - *Form Validation Library* didn't properly handle empty fields that were specified as an array.
- Fixed a bug (#2061) - *Routing Class* didn't properly sanitize directory, controller and function triggers with **enable_query_strings** set to TRUE.
- Fixed a bug - *SQLSRV* didn't support `escape_like_str()` or escaping an array of values.
- Fixed a bug - *Database Results* method `list_fields()` didn't reset its field pointer for the *mysql*, *mysqli* and *mssql* drivers.
- Fixed a bug (#73) - *Security Library* method `sanitize_filename()` could be tricked by an XSS attack.
- Fixed a bug (#2211) - *Migration Library* extensions couldn't execute `CI_Migration::__construct()`.
- Fixed a bug (#2255) - *Email Library* didn't apply `smtp_timeout` to socket reads and writes.
- Fixed a bug (#2239) - *Email Library* improperly handled the Subject when used with `bcc_batch_mode` resulting in `E_WARNING` messages and an empty Subject.
- Fixed a bug (#2234) - *Query Builder* didn't reset JOIN cache for write-type queries.
- Fixed a bug (#2298) - *Database Results* method `next_row()` kept returning the last row, allowing for infinite loops.
- Fixed a bug (#2236, #2639) - *Form Helper* functions `set_value()`, `set_select()`, `set_radio()`, `set_checkbox()` didn't parse array notation for keys if the rule was not present in the *Form Validation Library*.
- Fixed a bug (#2353) - *Query Builder* erroneously prefixed literal strings with **dbprefix**.
- Fixed a bug (#78) - *Cart Library* didn't allow non-English letters in product names.
- Fixed a bug (#77) - *Database Class* didn't properly handle the transaction "test mode" flag.
- Fixed a bug (#2380) - *URI Routing* method `fetch_method()` returned 'index' if the requested method name matches its controller name.
- Fixed a bug (#2388) - *Email Library* used to ignore attachment errors, resulting in broken emails being sent.
- Fixed a bug (#2498) - *Form Validation Library* rule **valid_base64** only checked characters instead of actual validity.
- Fixed a bug (#2425) - *OCI8* database driver's method `stored_procedure()` didn't log an error unless **db_debug** was set to TRUE.
- Fixed a bug (#2490) - *Database Class* method `query()` returning boolean instead of a result object when the PostgreSQL-specific *RETURNING* clause is used.
- Fixed a bug (#249) - *Cache Library* didn't properly handle Memcache(d) configurations with missing options.
- Fixed a bug (#180) - `config_item()` didn't take into account run-time configuration changes.
- Fixed a bug (#2551) - *Loader Library* method `library()` didn't properly check if a class that is being loaded already exists.
- Fixed a bug (#2560) - *Form Helper* function `form_open()` set the 'method="post"' attribute only if the passed attributes equaled an empty string.
- Fixed a bug (#2585) - *Query Builder* methods `min()`, `max()`, `avg()`, `sum()` didn't escape field names.
- Fixed an edge case (#2583) in the *Email Library* where *Suhosin* <<http://www.hardened-php.net/suhosin/>> blocked messages sent via `mail()` due to trailing newspaces in headers.
- Fixed a bug (#2590) - `log_message()` didn't actually cache the `CI_Log` class instance.

- Fixed a bug (#2609) - `get_config()` optional argument was only effective on first function call. Also, it can now add items, in addition to updating existing items.
- Fixed a bug in the 'postgre' *database* driver where the connection ID wasn't passed to `pg_escape_string()`.
- Fixed a bug (#33) - Script execution was terminated when an invalid cookie key was encountered.
- Fixed a bug (#2681) - `CI_Security::entity_decode()` used the `PREG_REPLACE_EVAL` flag, which is deprecated since PHP 5.5.
- Fixed a bug (#2691) - nested transactions could end in a deadlock when an error is encountered with `db_debug` set to TRUE.
- Fixed a bug (#2515) - `_exception_handler()` used to send the 200 "OK" HTTP status code and didn't stop script execution even on fatal errors.
- Fixed a bug - Redis *Caching* driver didn't handle connection failures properly.
- Fixed a bug (#2756) - *Database Class* executed the MySQL-specific `SET SESSION sql_mode` query for all drivers when the 'stricton' option is set.

10.5.2 Version 2.1.4

Release Date: July 8, 2013

- General Changes
 - Improved security in `xss_clean()`.

Bug fixes for 2.1.4

- Fixed a bug (#1936) - *Migration Library* method `latest()` had a typo when retrieving language values.
- Fixed a bug (#2021) - *Migration Library* configuration file was mistakenly using Windows style line feeds.
- Fixed a bug (#1273) - `E_NOTICE` being generated by *Query Builder's* `set_update_batch()` method.
- Fixed a bug (#2337) - *Email Library* method `print_debugger()` didn't apply `htmlspecialchars()` to headers.

10.5.3 Version 2.1.3

Release Date: October 8, 2012

- Core
 - *Common function* `is_loaded()` now returns a reference.

Bug fixes for 2.1.3

- Fixed a bug (#1543) - File-based *Caching* method `get_metadata()` used a non-existent array key to look for the TTL value.
- Fixed a bug (#1314) - *Session Library* method `sess_destroy()` didn't destroy the userdata array.
- Fixed a bug (#804) - *Profiler library* was trying to handle objects as strings in some cases, resulting in `E_WARNING` messages being issued by `htmlspecialchars()`.

- Fixed a bug (#1699) - *Migration Library* ignored the `$config['migration_path']` setting.
- Fixed a bug (#227) - *Input Library* allowed unconditional spoofing of HTTP clients' IP addresses through the `HTTP_CLIENT_IP` header.
- Fixed a bug (#907) - *Input Library* ignored `HTTP_X_CLUSTER_CLIENT_IP` and `HTTP_X_CLIENT_IP` headers when checking for proxies.
- Fixed a bug (#940) - `csrf_verify()` used to set the CSRF cookie while processing a POST request with no actual POST data, which resulted in validating a request that should be considered invalid.
- Fixed a bug (#499) - *Security Library* where a CSRF cookie was created even if `$config['csrf_protection']` is set to FALSE.
- Fixed a bug (#1715) - *Input Library* triggered `csrf_verify()` on CLI requests.
- Fixed a bug (#751) - *Query Builder* didn't properly handle cached field escaping overrides.
- Fixed a bug (#2004) - *Query Builder* didn't properly merge cached calls with non-cache ones.

10.5.4 Version 2.1.2

Release Date: June 29, 2012

- General Changes
 - Improved security in `xss_clean()`.

10.5.5 Version 2.1.1

Release Date: June 12, 2012

- General Changes
 - Fixed support for docx, xlsx files in `mimes.php`.
- Libraries
 - Further improved MIME type detection in the *File Uploading Library*.
 - Added support for IPv6 to the *Input Library*.
 - Added support for the IP format parameter to the *Form Validation Library*.
- Helpers
 - `url_title()` performance and output improved. You can now use any string as the word delimiter, but 'dash' and 'underscore' are still supported.

Bug fixes for 2.1.1

- Fixed a bug (#697) - A wrong array key was used in the *File Uploading Library* to check for mime-types.
- Fixed a bug - `form_open()` compared `$action` against `site_url()` instead of `base_url()`.
- Fixed a bug - `CI_Upload::_file_mime_type()` could've failed if `mime_content_type()` is used for the detection and returns FALSE.
- Fixed a bug (#538) - Windows paths were ignored when using the *Image Manipulation Library* to create a new file.

- Fixed a bug - When database caching was enabled, `$this->db->query()` checked the cache before binding variables which resulted in cached queries never being found.
- Fixed a bug - CSRF cookie value was allowed to be any (non-empty) string before being written to the output, making code injection a risk.
- Fixed a bug (#726) - PDO put a 'dbname' argument in its connection string regardless of the database platform in use, which made it impossible to use SQLite.
- Fixed a bug - `CI_DB_pdo_driver::num_rows()` was not returning properly value with SELECT queries, cause it was relying on `PDOStatement::rowCount()`.
- Fixed a bug (#1059) - `CI_Image_lib::clear()` was not correctly clearing all necessary object properties, namely width and height.

10.5.6 Version 2.1.0

Release Date: November 14, 2011

- General Changes
 - Callback validation rules can now accept parameters like any other validation rule.
 - Added `html_escape()` to *Common functions* to escape HTML output for preventing XSS.
- Helpers
 - Added `increment_string()` to *String Helper* to turn "foo" into "foo-1" or "foo-1" into "foo-2".
 - Altered form helper - made action on `form_open_multipart` helper function call optional. Fixes (#65)
 - `url_title()` will now trim extra dashes from beginning and end.
 - Improved speed of *String Helper's* `random_string()` method
- Database
 - Added a **CUBRID** driver to the *Database Driver*. Thanks to the CUBRID team for supplying this patch.
 - Added a PDO driver to the *Database Driver*.
 - Typecast limit and offset in the *Database Driver* to integers to avoid possible injection.
 - Added additional option 'none' for the optional third argument for `$this->db->like()` in the *Database Driver*.
 - Added `$this->db->insert_batch()` support to the OCI8 (Oracle) driver.
 - Added failover if the main connections in the config should fail
- Libraries
 - Changed `$this->cart->insert()` in the *Cart Library* to return the Row ID if a single item was inserted successfully.
 - Added support to set an optional parameter in your callback rules of validation using the *Form Validation Library*.
 - Added a *Migration library* to assist with applying incremental updates to your database schema.
 - Driver children can be located in any package path.
 - Added `max_filename_increment` config setting for Upload library.
 - Added `is_unique` to the *Form Validation library*.

- Added `$config['use_page_numbers']` to the *Pagination library*, which enables real page numbers in the URI.
- Added TLS and SSL Encryption for SMTP.
- Core
 - Changed private functions in `CI_URI` to protected so `MY_URI` can override them.
 - Removed `CI_CORE` boolean constant from `CodeIgniter.php` (no longer Reactor and Core versions).

Bug fixes for 2.1.0

- Fixed #378 Robots identified as regular browsers by the User Agent class.
- If a config class was loaded first then a library with the same name is loaded, the config would be ignored.
- Fixed a bug (Reactor #19) where 1) the `404_override` route was being ignored in some cases, and 2) auto-loaded libraries were not available to the `404_override` controller when a controller existed but the requested method did not.
- Fixed a bug (Reactor #89) where MySQL export would fail if the table had hyphens or other non alphanumeric/underscore characters.
- Fixed a bug (#105) that stopped query errors from being logged unless database debugging was enabled
- Fixed a bug (#160) - Removed unneeded array copy in the file cache driver.
- Fixed a bug (#150) - `field_data()` now correctly returns column length.
- Fixed a bug (#8) - `load_class()` now looks for core classes in `APPPATH` first, allowing them to be replaced.
- Fixed a bug (#24) - ODBC database driver called incorrect parent in `__construct()`.
- Fixed a bug (#85) - OCI8 (Oracle) database `escape_str()` function did not escape correct.
- Fixed a bug (#344) - Using schema found in *Saving Session Data to a Database*, system would throw error “user_data does not have a default value” when deleting then creating a session.
- Fixed a bug (#112) - OCI8 (Oracle) driver didn’t pass the configured database character set when connecting.
- Fixed a bug (#182) - OCI8 (Oracle) driver used to re-execute the statement whenever `num_rows()` is called.
- Fixed a bug (#82) - WHERE clause field names in the DB `update_string()` method were not escaped, resulting in failed queries in some cases.
- Fixed a bug (#89) - Fix a variable type mismatch in DB `display_error()` where an array is expected, but a string could be set instead.
- Fixed a bug (#467) - Suppress warnings generated from `get_magic_quotes_gpc()` (deprecated in PHP 5.4)
- Fixed a bug (#484) - First time `_csrf_set_hash()` is called, hash is never set to the cookie (in `Security.php`).
- Fixed a bug (#60) - Added `_file_mime_type()` method to the *File Uploading Library* in order to fix a possible MIME-type injection.
- Fixed a bug (#537) - Support for all wav type in browser.
- Fixed a bug (#576) - Using `ini_get()` function to detect if apc is enabled or not.
- Fixed invalid date time format in *Date helper* and *XMLRPC library*.
- Fixed a bug (#200) - MySQL queries would be malformed after calling `db->count_all()` then `db->get()`.

10.5.7 Version 2.0.3

Release Date: August 20, 2011

- Security
 - An improvement was made to the MySQL and MySQLi drivers to prevent exposing a potential vector for SQL injection on sites using multi-byte character sets in the database client connection. An incompatibility in PHP versions < 5.2.3 and MySQL < 5.0.7 with *mysql_set_charset()* creates a situation where using multi-byte character sets on these environments may potentially expose a SQL injection attack vector. Latin-1, UTF-8, and other “low ASCII” character sets are unaffected on all environments.

If you are running or considering running a multi-byte character set for your database connection, please pay close attention to the server environment you are deploying on to ensure you are not vulnerable.
- General Changes
 - Fixed a bug where there was a misspelling within a code comment in the *index.php* file.
 - Added Session Class userdata to the output profiler. Additionally, added a show/hide toggle on HTTP Headers, Session Data and Config Variables.
 - Removed internal usage of the EXT constant.
 - Visual updates to the *welcome_message* view file and default error templates. Thanks to [danijelb](#) for the pull request.
 - Added *insert_batch()* function to the PostgreSQL database driver. Thanks to [epallerols](#) for the patch.
 - Added “application/x-csv” to *mimes.php*.
 - Fixed a bug where *Email library* attachments with a “.” in the name would using invalid MIME-types.
- Helpers
 - Added an optional third parameter to *heading()* which allows adding html attributes to the rendered heading tag.
 - *form_open()* now only adds a hidden (Cross-site Reference Forgery) protection field when the form’s action is internal and is set to the post method. (Reactor #165)
 - Re-worked *plural()* and *singular()* functions in the *Inflector helper* to support considerably more words.
- Libraries
 - Altered Session to use a longer match against the *user_agent* string. See upgrade notes if using database sessions.
 - Added *\$this->db->set_dbprefix()* to the *Database Driver*.
 - Changed *\$this->cart->insert()* in the *Cart Library* to return the Row ID if a single item was inserted successfully.
 - Added *\$this->load->get_var()* to the *Loader library* to retrieve global vars set with *\$this->load->view()* and *\$this->load->vars()*.
 - Changed *\$this->db->having()* to insert quotes using *escape()* rather than *escape_str()*.

Bug fixes for 2.0.3

- Added ENVIRONMENT to reserved constants. (Reactor #196)
- Changed server check to ensure SCRIPT_NAME is defined. (Reactor #57)

- Removed APPPATH.'third_party' from the packages autoloader to negate needless file stats if no packages exist or if the developer does not load any other packages by default.
- Fixed a bug (Reactor #231) where Sessions Library database table example SQL did not contain an index on last_activity. See *Upgrade Notes*.
- Fixed a bug (Reactor #229) where the Sessions Library example SQL in the documentation contained incorrect SQL.
- Fixed a bug (Core #340) where when passing in the second parameter to `$this->db->select()`, column names in subsequent queries would not be properly escaped.
- Fixed issue #199 - Attributes passed as string does not include a space between it and the opening tag.
- Fixed a bug where the method `$this->cart->total_items()` from *Cart Library* now returns the sum of the quantity of all items in the cart instead of your total count.
- Fixed a bug where not setting 'null' when adding fields in `db_forge` for mysql and mysqli drivers would default to NULL instead of NOT NULL as the docs suggest.
- Fixed a bug where using `$this->db->select_max()`, `$this->db->select_min()`, etc could throw notices. Thanks to w43l for the patch.
- Replace checks for STDIN with `php_sapi_name() == 'cli'` which on the whole is more reliable. This should get parameters in crontab working.

10.5.8 Version 2.0.2

Release Date: April 7, 2011 Hg Tag: v2.0.2

- General changes
 - The *Security library* was moved to the core and is now loaded automatically. Please remove your loading calls.
 - The `CI_SHA` class is now deprecated. All supported versions of PHP provide a `sha1()` function.
 - `constants.php` will now be loaded from the environment folder if available.
 - Added language key error logging
 - Made Environment Support optional. Comment out or delete the constant to stop environment checks.
 - Added Environment Support for Hooks.
 - Added `CI_Prefix` to the *Cache driver*.
 - Added *CLI usage* documentation.
- Helpers
 - Removed the previously deprecated `dohash()` from the *Security helper*; use `do_hash()` instead.
 - Changed the 'plural' function so that it doesn't ruin the capitalization of your string. It also take into consideration acronyms which are all caps.
- Database
 - `$this->db->count_all_results()` will now return an integer instead of a string.

Bug fixes for 2.0.2

- Fixed a bug (Reactor #145) where the Output Library had `parse_exec_vars` set to protected.
- Fixed a bug (Reactor #80) where `is_really_writable` would create an empty file when on Windows or with `safe_mode` enabled.
- Fixed various bugs with User Guide.
- Added `is_cli_request()` method to documentation for *Input class*.
- Added `form_validation_lang` entries for `decimal`, `less_than` and `greater_than`.
- [Fixed issue #153](#) Escape Str Bug in MSSQL driver.
- [Fixed issue #172](#) Google Chrome 11 posts incorrectly when action is empty.

10.5.9 Version 2.0.1

Release Date: March 15, 2011 Hg Tag: v2.0.1

- General changes
 - Added `$config['cookie_secure']` to the config file to allow requiring a secure (HTTPS) in order to set cookies.
 - Added the constant `CI_CORE` to help differentiate between Core: TRUE and Reactor: FALSE.
 - Added an `ENVIRONMENT` constant in `index.php`, which affects PHP error reporting settings, and optionally, which configuration files are loaded (see below). Read more on the *Handling Environments* page.
 - Added support for *environment-specific* configuration files.
- Libraries
 - Added `decimal`, `less_than` and `greater_than` rules to the *Form validation Class*.
 - *Input Class* methods `post()` and `get()` will now return a full array if the first argument is not provided.
 - Secure cookies can now be made with the `set_cookie()` helper and *Input Class* method.
 - Added `set_content_type()` to *Output Class* to set the output Content-Type HTTP header based on a MIME Type or a `config/mimes.php` array key.
 - *Output Class* will now support method chaining.
- Helpers
 - Changed the logic for `form_open()` in *Form helper*. If no value is passed it will submit to the current URL.

Bug fixes for 2.0.1

- CLI requests can now be run from any folder, not just when CD'ed next to `index.php`.
- Fixed issue #41: Added `audio/mp3` mime type to `mp3`.
- Fixed a bug (Core #329) where the file caching driver referenced the incorrect cache directory.
- Fixed a bug (Reactor #69) where the SHA1 library was named incorrectly.

10.5.10 Version 2.0.0

Release Date: January 28, 2011 Hg Tag: v2.0.0

- General changes
 - PHP 4 support is removed. CodeIgniter now requires PHP 5.1.6.
 - Scaffolding, having been deprecated for a number of versions, has been removed.
 - Plugins have been removed, in favor of Helpers. The CAPTCHA plugin has been converted to a Helper and *documented*. The JavaScript calendar plugin was removed due to the ready availability of great JavaScript calendars, particularly with jQuery.
 - Added new special Library type: *Drivers*.
 - Added full query-string support. See the config file for details.
 - Moved the application folder outside of the system folder.
 - Moved system/cache and system/logs directories to the application directory.
 - Added routing overrides to the main index.php file, enabling the normal routing to be overridden on a per “index” file basis.
 - Added the ability to set config values (or override config values) directly from data set in the main index.php file. This allows a single application to be used with multiple front controllers, each having its own config values.
 - Added \$config['directory_trigger'] to the config file so that a controller sub-directory can be specified when running _GET strings instead of URI segments.
 - Added ability to set “Package” paths - specific paths where the Loader and Config classes should try to look first for a requested file. This allows distribution of sub-applications with their own libraries, models, config files, etc. in a single “package” directory. See the *Loader class* documentation for more details.
 - In-development code is now hosted at [BitBucket](#).
 - Removed the deprecated Validation Class.
 - Added CI_ Prefix to all core classes.
 - Package paths can now be set in application/config/autoload.php.
 - *Upload library* file_name can now be set without an extension, the extension will be taken from the uploaded file instead of the given name.
 - In *Database Forge* the name can be omitted from \$this->dbforge->modify_column()'s 2nd param if you aren't changing the name.
 - \$config['base_url'] is now empty by default and will guess what it should be.
 - Enabled full Command Line Interface compatibility with config['uri_protocol'] = 'CLI';.
- Libraries
 - Added a *Cache driver* with APC, memcached, and file-based support.
 - Added \$prefix, \$suffix and \$first_url properties to *Pagination library*.
 - Added the ability to suppress first, previous, next, last, and page links by setting their values to FALSE in the *Pagination library*.
 - Added *Security library*, which now contains the xss_clean function, filename_security function and other security related functions.
 - Added CSRF (Cross-site Reference Forgery) protection to the *Security library*.

- Added \$parse_exec_vars property to Output library.
- Added ability to enable / disable individual sections of the *Profiler*
- Added a wildcard option \$config['allowed_types'] = '*' to the *File Uploading Class*.
- Added an 'object' config variable to the XML-RPC Server library so that one can specify the object to look for requested methods, instead of assuming it is in the \$CI superobject.
- Added "is_object" into the list of unit tests capable of being run.
- Table library will generate an empty cell with a blank string, or NULL value.
- Added ability to set tag attributes for individual cells in the Table library
- Added a parse_string() method to the *Parser Class*.
- Added HTTP headers and Config information to the *Profiler* output.
- Added Chrome and Flock to the list of detectable browsers by browser() in the *User Agent Class*.
- The *Unit Test Class* now has an optional "notes" field available to it, and allows for discrete display of test result items using \$this->unit->set_test_items().
- Added a \$xss_clean class variable to the XMLRPC library, enabling control over the use of the Security library's xss_clean() method.
- Added a download() method to the *FTP library*
- Changed do_xss_clean() to return FALSE if the uploaded file fails XSS checks.
- Added stripslashes() and trim()ing of double quotes from \$_FILES type value to standardize input in Upload library.
- Added a second parameter (boolean) to \$this->zip->read_dir('/path/to/directory', FALSE) to remove the preceding trail of empty folders when creating a Zip archive. This example would contain a zip with "directory" and all of its contents.
- Added ability in the Image Library to handle PNG transparency for resize operations when using the GD lib.
- Modified the Session class to prevent use if no encryption key is set in the config file.
- Added a new config item to the Session class sess_expire_on_close to allow sessions to auto-expire when the browser window is closed.
- Improved performance of the Encryption library on servers where Mcrypt is available.
- Changed the default encryption mode in the Encryption library to CBC.
- Added an encode_from_legacy() method to provide a way to transition encrypted data from CodeIgniter 1.x to CodeIgniter 2.x. Please see the *upgrade instructions* for details.
- Altered Form_Validation library to allow for method chaining on set_rules(), set_message() and set_error_delimiters() functions.
- Altered Email Library to allow for method chaining.
- Added request_headers(), get_request_header() and is_ajax_request() to the input class.
- Altered *User agent library* so that is_browser(), is_mobile() and is_robot() can optionally check for a specific browser or mobile device.
- Altered *Input library* so that post() and get() will return all POST and GET items (respectively) if there are no parameters passed in.

- Database

- *database configuration.*
- Added autoinit value to *database configuration.*
- Added stricton value to *database configuration.*
- Added database_exists() to the *Database Utilities Class.*
- Semantic change to db->version() function to allow a list of exceptions for databases with functions to return version string instead of specially formed SQL queries. Currently this list only includes Oracle and SQLite.
- Fixed a bug where driver specific table identifier protection could lead to malformed queries in the field_data() functions.
- Fixed a bug where an undefined class variable was referenced in database drivers.
- Modified the database errors to show the filename and line number of the problematic query.
- Removed the following deprecated functions: orwhere, orlike, groupby, orhaving, orderby, getwhere.
- Removed deprecated _drop_database() and _create_database() functions from the db utility drivers.
- Improved dbforge create_table() function for the Postgres driver.
- **Helpers**
 - Added convert_accented_characters() function to *text helper.*
 - Added accept-charset to the list of inserted attributes of form_open() in the *Form Helper.*
 - Deprecated the dohash() function in favour of do_hash() for naming consistency.
 - Non-backwards compatible change made to get_dir_file_info() in the *File Helper.* No longer recurses by default so as to encourage responsible use (this function can cause server performance issues when used without caution).
 - Modified the second parameter of directory_map() in the *Directory Helper* to accept an integer to specify recursion depth.
 - Modified delete_files() in the *File Helper* to return FALSE on failure.
 - Added an optional second parameter to byte_format() in the *Number Helper* to allow for decimal precision.
 - Added alpha, and sha1 string types to random_string() in the *String Helper.*
 - Modified prep_url() so as to not prepend <http://> if the supplied string already has a scheme.
 - Modified get_file_info in the file helper, changing filectime() to filemtime() for dates.
 - Modified smiley_js() to add optional third parameter to return only the javascript with no script tags.
 - The img() function of the *HTML helper* will now generate an empty string as an alt attribute if one is not provided.
 - If CSRF is enabled in the application config file, form_open() will automatically insert it as a hidden field.
 - Added sanitize_filename() into the *Security helper.*
 - Added ellipsis() to the *Text Helper*
 - Added elements() to the *Array Helper*
- **Other Changes**
 - Added an optional second parameter to show_404() to disable logging.
 - Updated loader to automatically apply the sub-class prefix as an option when loading classes. Class names can be prefixed with the standard “CI_” or the same prefix as the subclass prefix, or no prefix at all.

- Increased randomness with `is_really_writable()` to avoid file collisions when hundreds or thousands of requests occur at once.
- Switched some `DIR_WRITE_MODE` constant uses to `FILE_WRITE_MODE` where files and not directories are being operated on.
- `get_mime_by_extension()` is now case insensitive.
- Added “default” to the list *Reserved Names*.
- Added ‘application/x-msdownload’ for .exe files and ‘application/x-gzip-compressed’ for .tgz files to `config/mimes.php`.
- Updated the output library to no longer compress output or send content-length headers if the server runs with `zlib.output_compression` enabled.
- Eliminated a call to `is_really_writable()` on each request unless it is really needed (Output caching)
- Documented `append_output()` in the *Output Class*.
- Documented a second argument in the `decode()` function for the *Encryption Class*.
- Documented `db->close()`.
- Updated the router to support a default route with any number of segments.
- Moved `_remove_invisible_characters()` function from the *Security Library* to *common functions*.
- Added audio/mpeg3 as a valid mime type for MP3.

Bug fixes for 2.0.0

- Fixed a bug where you could not change the User-Agent when sending email.
- Fixed a bug where the Output class would send incorrect cached output for controllers implementing their own `_output()` method.
- Fixed a bug where a failed query would not have a saved query execution time causing errors in the Profiler
- Fixed a bug that was writing log entries when multiple identical helpers and plugins were loaded.
- Fixed assorted user guide typos or examples (#10693, #8951, #7825, #8660, #7883, #6771, #10656).
- Fixed a language key in the profiler: “profiler_no_memory_usage” to “profiler_no_memory”.
- Fixed an error in the Zip library that didn’t allow downloading on PHP 4 servers.
- Fixed a bug in the Form Validation library where fields passed as rule parameters were not being translated (#9132)
- Modified inflector helper to properly pluralize words that end in ‘ch’ or ‘sh’
- Fixed a bug in `xss_clean()` that was not allowing hyphens in query strings of submitted URLs.
- Fixed bugs in `get_dir_file_info()` and `get_file_info()` in the File Helper with recursion, and file paths on Windows.
- Fixed a bug where Active Record override parameter would not let you disable Active Record if it was enabled in your database config file.
- Fixed a bug in `reduce_double_slashes()` in the String Helper to properly remove duplicate leading slashes (#7585)
- Fixed a bug in `values_parsing()` of the XML-RPC library which prevented NULL variables typed as ‘string’ from being handled properly.
- Fixed a bug where `form_open_multipart()` didn’t accept string attribute arguments (#10930).

- Fixed a bug (#10470) where `get_mime_by_extension()` was case sensitive.
- Fixed a bug where some error messages for the SQLite and Oracle drivers would not display.
- Fixed a bug where files created with the Zip Library would result in file creation dates of 1980.
- Fixed a bug in the Session library that would result in PHP error when attempting to store values with objects.
- Fixed a bug where extending the Controller class would result in a fatal PHP error.
- Fixed a PHP Strict Standards Error in the `index.php` file.
- Fixed a bug where `getimagesize()` was being needlessly checked on non-image files in `is_allowed_type()`.
- Fixed a bug in the Encryption library where an empty key was not triggering an error.
- Fixed a bug in the Email library where CC and BCC recipients were not reset when using the `clear()` method (#109).
- Fixed a bug in the URL Helper where `prep_url()` could cause a PHP error on PHP versions < 5.1.2.
- Added a log message in `core/output` if the cache directory config value was not found.
- Fixed a bug where multiple libraries could not be loaded by passing an array to `load->library()`
- Fixed a bug in the html helper where too much white space was rendered between the `src` and `alt` tags in the `img()` function.
- Fixed a bug in the profilers `_compile_queries()` function.
- Fixed a bug in the date helper where the `DATE_ISO8601` variable was returning an incorrectly formatted date string.

10.5.11 Version 1.7.2

Release Date: September 11, 2009 Hg Tag: v1.7.2

- Libraries
 - Added a new *Cart Class*.
 - Added the ability to pass `$config['file_name']` for the *File Uploading Class* and rename the uploaded file.
 - Changed order of listed user-agents so Safari would more accurately report itself. (#6844)
- Database
 - Switched from using `gettype()` in `escape()` to `is_*` methods, since future PHP versions might change its output.
 - Updated all database drivers to handle arrays in `escape_str()`
 - Added `escape_like_str()` method for escaping strings to be used in LIKE conditions
 - Updated Active Record to utilize the new LIKE escaping mechanism.
 - Added `reconnect()` method to DB drivers to try to keep alive / reestablish a connection after a long idle.
 - Modified MSSQL driver to use `mssql_get_last_message()` for error messages.
- Helpers
 - Added `form_multiselect()` to the *Form helper*.
 - Modified `form_hidden()` in the *Form helper* to accept multi-dimensional arrays.

- Modified `form_prep()` in the *Form helper* to keep track of prepped fields to avoid multiple prep/mutation from subsequent calls which can occur when using Form Validation and form helper functions to output form fields.
- Modified `directory_map()` in the *Directory helper* to allow the inclusion of hidden files, and to return `FALSE` on failure to read directory.
- Modified the *Smiley helper* to work with multiple fields and insert the smiley at the last known cursor position.
- General
 - Compatible with PHP 5.3.0.
 - Modified `show_error()` to allow sending of HTTP server response codes.
 - Modified `show_404()` to send 404 status code, removing non-CGI compatible `header()` statement from `error_404.php` template.
 - Added `set_status_header()` to the *Common functions* to allow use when the Output class is unavailable.
 - Added `is_php()` to *Common functions* to facilitate PHP version comparisons.
 - Added 2 CodeIgniter “cheatsheets” (thanks to DesignFellow.com for this contribution).

Bug fixes for 1.7.2

- Fixed assorted user guide typos or examples (#6743, #7214, #7516, #7287, #7852, #8224, #8324, #8349).
- Fixed a bug in the Form Validation library where multiple callbacks weren’t working (#6110)
- doctype helper default value was missing a “1”.
- Fixed a bug in the language class when outputting an error for an unfound file.
- Fixed a bug in the Calendar library where the shortname was output for “May”.
- Fixed a bug with `ORIG_PATH_INFO` that was allowing URIs of just a slash through.
- Fixed a fatal error in the Oracle and ODBC drivers (#6752)
- Fixed a bug where `xml_from_result()` was checking for a nonexistent method.
- Fixed a bug where Database Forge’s `add_column` and `modify_column` were not looping through when sent multiple fields.
- Fixed a bug where the File Helper was using ‘/’ instead of the `DIRECTORY_SEPARATOR` constant.
- Fixed a bug to prevent PHP errors when attempting to use `sendmail` on servers that have manually disabled the `PHP popen()` function.
- Fixed a bug that would cause PHP errors in XML-RPC data if the PHP data type did not match the specified XML-RPC type.
- Fixed a bug in the XML-RPC class with parsing `dateTime.iso8601` data types.
- Fixed a case sensitive string replacement in `xss_clean()`
- Fixed a bug in `form_textarea()` where form data was not prepped correctly.
- Fixed a bug in `form_prep()` causing it to not preserve entities in the user’s original input when called back into a form element
- Fixed a bug in `_protect_identifiers()` where the swap prefix (`$swap_pre`) was not being observed.

- Fixed a bug where the 400 status header sent with the ‘disallowed URI characters’ was not compatible with CGI environments.
- Fixed a bug in the typography class where heading tags could have paragraph tags inserted when using `auto_typography()`.

10.5.12 Version 1.7.1

Release Date: February 10, 2009 Hg Tag: 1.7.1

- Libraries
 - Fixed an arbitrary script execution security flaw (#6068) in the Form Validation library (thanks to hkk)
 - Changed default current page indicator in the Pagination library to use `` instead of ``
 - A “HTTP/1.1 400 Bad Request” header is now sent when disallowed characters are encountered.
 - Added `<big>`, `<small>`, `<q>`, and `<tt>` to the Typography parser’s inline elements.
 - Added more accurate error reporting for the Email library when using `sendmail`.
 - Removed a strict type check from the `rotate()` function of the *Image Manipulation Class*.
 - Added enhanced error checking in file saving in the Image library when using the GD lib.
 - Added an additional newline between multipart email headers and the MIME message text for better compatibility with a variety of MUAs.
 - Made modest improvements to efficiency and accuracy of `explode_name()` in the Image lib.
- Database
 - Added `where_in` to the list of expected arguments received by `delete()`.
- Helpers
 - Added the ability to have optgroups in `form_dropdown()` within the *form helper*.
 - Added a `doctype()` function to the *HTML helper*.
 - Added ability to force lowercase for `url_title()` in the *URL helper*.
 - Changed the default “type” of `form_button()` to “button” from “submit” in the *form helper*.
 - Changed `redirect()` in the URL helper to allow redirections to URLs outside of the CI site.
 - Updated `get_cookie()` to try to fetch the cookie using the global cookie prefix if the requested cookie name doesn’t exist.
- Other Changes
 - Improved security in `xss_clean()` to help prevent attacks targeting Internet Explorer.
 - Added ‘application/msexcel’ to `config/mimes.php` for .xls files.
 - Added ‘proxy_ips’ config item to whitelist reverse proxy servers from which to trust the `HTTP_X_FORWARDED_FOR` header to determine the visitor’s IP address.
 - Improved accuracy of `Upload::is_allowed_filetype()` for images (#6715)

Bug fixes for 1.7.1

- Database
 - Fixed a bug when doing ‘random’ on order_by() (#5706).
 - Fixed a bug where adding a primary key through Forge could fail (#5731).
 - Fixed a bug when using DB cache on multiple databases (#5737).
 - Fixed a bug where TRUNCATE was not considered a “write” query (#6619).
 - Fixed a bug where csv_from_result() was checking for a nonexistent method.
 - Fixed a bug _protect_identifiers() where it was improperly removing all pipe symbols from items
- Fixed assorted user guide typos or examples (#5998, #6093, #6259, #6339, #6432, #6521).
- Fixed a bug in the MySQLi driver when no port is specified
- Fixed a bug (#5702), in which the field label was not being fetched properly, when “matching” one field to another.
- Fixed a bug in which identifiers were not being escaped properly when reserved characters were used.
- Fixed a bug with the regular expression used to protect submitted paragraph tags in auto typography.
- Fixed a bug where double dashes within tag attributes were being converted to em dash entities.
- Fixed a bug where double spaces within tag attributes were being converted to non-breaking space entities.
- Fixed some accuracy issues with curly quotes in Typography::format_characters()
- Changed a few docblock comments to reflect actual return values.
- Fixed a bug with high ascii characters in subject and from email headers.
- Fixed a bug in xss_clean() where whitespace following a validated character entity would not be preserved.
- Fixed a bug where HTML comments and <pre> tags were being parsed in Typography::auto_typography().
- Fixed a bug with non-breaking space cleanup in Typography::auto_typography().
- Fixed a bug in database escaping where a compound statement (ie: SUM()) wasn’t handled correctly with database prefixes.
- Fixed a bug when an opening quote is preceded by a paragraph tag and immediately followed by another tag.
- Fixed a bug in the Text Helper affecting some locales where word_censor() would not work on words beginning or ending with an accented character.
- Fixed a bug in the Text Helper character limiter where the provided limit intersects the last word of the string.
- Fixed a bug (#6342) with plural() in the Inflection helper with words ending in “y”.
- Fixed bug (#6517) where Routed URI segments returned by URI::rsegment() method were incorrect for the default controller.
- Fixed a bug (#6706) in the Security Helper where xss_clean() was using a deprecated second argument.
- Fixed a bug in the URL helper url_title() function where trailing periods were allowed at the end of a URL.
- Fixed a bug (#6669) in the Email class when CRLF’s are used for the newline character with headers when used with the “mail” protocol.
- Fixed a bug (#6500) where URI::A_filter_uri() was exit()ing an error instead of using show_error().
- Fixed a bug (#6592) in the File Helper where get_dir_file_info() where recursion was not occurring properly.

- Tweaked `Typography::auto_typography()` for some edge-cases.

10.5.13 Version 1.7

Release Date: October 23, 2008 Hg Tag: 1.7.0

- Libraries
 - Added a new *Form Validation Class*. It simplifies setting rules and field names, supports arrays as field names, allows groups of validation rules to be saved in a config file, and adds some helper functions for use in view files. **Please note that the old Validation class is now deprecated.** We will leave it in the library folder for some time so that existing applications that use it will not break, but you are encouraged to migrate to the new version.
 - Updated the *Sessions class* so that any custom data being saved gets stored to a database rather than the session cookie (assuming you are using a database to store session data), permitting much more data to be saved.
 - Added the ability to store libraries in subdirectories within either the main “libraries” or the local application “libraries” folder. Please see the *Loader class* for more info.
 - Added the ability to assign library objects to your own variable names when you use `$this->load->library()`. Please see the *Loader class* for more info.
 - Added controller class/method info to *Profiler class* and support for multiple database connections.
 - Improved the “auto typography” feature and moved it out of the helper into its own *Typography Class*.
 - Improved performance and accuracy of `xss_clean()`, including reduction of false positives on image/file tests.
 - Improved *Parser class* to allow multiple calls to the `parse()` function. The output of each is appended in the output.
 - Added `max_filename` option to set a file name length limit in the *File Upload Class*.
 - Added `set_status_header()` function to *Output class*.
 - Modified *Pagination class* to only output the “First” link when the link for page one would not be shown.
 - Added support for `mb_strlen` in the *Form Validation class* so that multi-byte languages will calculate string lengths properly.
- Database
 - Improved Active Record class to allow full path column and table names: `hostname.database.table.column`. Also improved the alias handling.
 - Improved how table and column names are escaped and prefixed. It now honors full path names when adding prefixes and escaping.
 - Added Active Record caching feature to “update” and “delete” functions.
 - Added removal of non-printing control characters in `escape_str()` of DB drivers that do not have native PHP escaping mechanisms (mssql, oci8, odbc), to avoid potential SQL errors, and possible sources of SQL injection.
 - Added port support to MySQL, MySQLi, and MS SQL database drivers.
 - Added driver name variable in each DB driver, based on bug report #4436.
- Helpers

- Added several new “setting” functions to the *Form helper* that allow POST data to be retrieved and set into forms. These are intended to be used on their own, or with the new *Form Validation Class*.
- Added `current_url()` and `uri_segments()` to *URL helper*.
- Altered `auto_link()` in the *URL helper* so that email addresses with “+” included will be linked.
- Added `meta()` function to *HTML helper*.
- Improved accuracy of calculations in *Number helper*.
- Removed added newlines (“\n”) from most form and html helper functions.
- Tightened up validation in the *Date helper* function `human_to_unix()`, and eliminated the POSIX regex.
- Updated *Date helper* to match the world’s current time zones and offsets.
- Modified `url_title()` in the *URL helper* to remove characters and digits that are part of character entities, to allow dashes, underscores, and periods regardless of the `$separator`, and to allow uppercase characters.
- Added support for arbitrary attributes in `anchor_popup()` of the *URL helper*.
- Other Changes
 - Added *PHP Style Guide* to docs.
 - Added sanitization in `xss_clean()` for a deprecated HTML tag that could be abused in user input in Internet Explorer.
 - Added a few openxml document mime types, and an additional mobile agent to `mimes.php` and `user_agents.php` respectively.
 - Added a file lock check during caching, before trying to write to the file.
 - Modified Cookie key cleaning to unset a few troublesome key names that can be present in certain environments, preventing CI from halting execution.
 - Changed the output of the profiler to use style attribute rather than clear, and added the id “codeigniter_profiler” to the container div.

Bug fixes for 1.7.0

- Fixed bug in `xss_clean()` that could remove some desirable tag attributes.
- Fixed assorted user guide typos or examples (#4807, #4812, #4840, #4862, #4864, #4899, #4930, #5006, #5071, #5158, #5229, #5254, #5351).
- Fixed an edit from 1.6.3 that made the `$robots` array in `user_agents.php` go poof.
- Fixed a bug in the *Email library* with quoted-printable encoding improperly encoding space and tab characters.
- Modified XSS sanitization to no longer add semicolons after `&[single letter]`, such as in M&M’s, B&B, etc.
- Modified XSS sanitization to no longer strip XHTML image tags of closing slashes.
- Fixed a bug in the Session class when database sessions are used where upon session update all userdata would be errantly written to the session cookie.
- Fixed a bug (#4536) in backups with the MySQL driver where some legacy code was causing certain characters to be double escaped.
- Fixed a routing bug (#4661) that occurred when the default route pointed to a subfolder.
- Fixed the spelling of “Dhaka” in the `timezone_menu()` function of the *Date helper*.
- Fixed the spelling of “raspberry” in `config/smileys.php`.

- Fixed incorrect parenthesis in `form_open()` function (#5135).
- Fixed a bug that was ignoring case when comparing controller methods (#4560).
- Fixed a bug (#4615) that was not setting SMTP authorization settings when using the initialize function.
- Fixed a bug in `highlight_code()` in the *Text helper* that would leave a stray `` in certain cases.
- Fixed Oracle bug (#3306) that was preventing multiple queries in one action.
- Fixed ODBC bug that was ignoring connection params due to its use of a constructor.
- Fixed a DB driver bug with `num_rows()` that would cause an error with the Oracle driver.
- Fixed MS SQL bug (#4915). Added brackets around database name in MS SQL driver when selecting the database, in the event that reserved characters are used in the name.
- Fixed a DB caching bug (4718) in which the path was incorrect when no URI segments were present.
- Fixed `Image_lib` class bug #4562. A path was not defined for NetPBM.
- Fixed `Image_lib` class bug #4532. When cropping an image with identical height/width settings on output, a copy is made.
- Fixed `DB_driver` bug (4900), in which a database error was not being logged correctly.
- Fixed DB backup bug in which field names were not being escaped.
- Fixed a DB Active Record caching bug in which multiple calls to cached data were not being honored.
- Fixed a bug in the Session class that was disallowing slashes in the serialized array.
- Fixed a Form Validation bug in which the “isset” error message was being triggered by the “required” rule.
- Fixed a spelling error in a Loader error message.
- Fixed a bug (5050) with IP validation with empty segments.
- Fixed a bug in which the parser was being greedy if multiple identical sets of tags were encountered.

10.5.14 Version 1.6.3

Release Date: June 26, 2008 Hg Tag: v1.6.3

Version 1.6.3 is a security and maintenance release and is recommended for all users.

- Database
 - Modified MySQL/MySQLi Forge class to give explicit names to keys
 - Added ability to set multiple column non-primary keys to the *Forge class*
 - Added ability to set additional database config values in *DSN connections* via the query string.
- Libraries
 - Set the mime type check in the *Upload class* to reference the global mimes variable.
 - Added support for query strings to the *Pagination class*, automatically detected or explicitly declared.
 - Added `get_post()` to the *Input class*.
 - Documented `get()` in the *Input class*.
 - Added the ability to automatically output language items as form labels in the *Language class*.
- Helpers
 - Added a *Language helper*.

- Added a *Number helper*.
 - *Form helper* refactored to allow `form_open()` and `form_fieldset()` to accept arrays or strings as arguments.
- Other changes
 - Improved security in `xss_clean()`.
 - Removed an unused Router reference in `_display_cache()`.
 - Added ability to use `xss_clean()` to test images for XSS, useful for upload security.
 - Considerably expanded list of mobile user-agents in `config/user_agents.php`.
 - Charset information in the userguide has been moved above title for internationalization purposes (#4614).
 - Added “Using Associative Arrays In a Request Parameter” example to the *XMLRPC userguide page*.
 - Removed `maxlength` and `size` as automatically added attributes of `form_input()` in the *form helper*.
 - Documented the language file use of `byte_format()` in the *number helper*.

Bug fixes for 1.6.3

- Added a language key for `valid_emails` in `validation_lang.php`.
- Amended fixes for bug (#3419) with parsing DSN database connections.
- Moved the `_has_operator()` function (#4535) into `DB_driver` from `DB_active_rec`.
- Fixed a syntax error in `upload_lang.php`.
- Fixed a bug (#4542) with a regular expression in the Image library.
- Fixed a bug (#4561) where `orhaving()` wasn’t properly passing values.
- Removed some unused variables from the code (#4563).
- Fixed a bug where `having()` was not adding an `=` into the statement (#4568).
- Fixed assorted user guide typos or examples (#4574, #4706).
- Added quoted-printable headers to Email class when the multi-part override is used.
- Fixed a double opening `<p>` tag in the index pages of each system directory.

10.5.15 Version 1.6.2

Release Date: May 13, 2008 Hg Tag: 1.6.2

- Active Record
 - Added the ability to prevent escaping in `having()` clauses.
 - Added `rename_table()` into *DBForge*.
 - Fixed a bug that wasn’t allowing escaping to be turned off if the value of a query was NULL.
 - DB Forge is now assigned to any models that exist after loading (#3457).
- Database
 - Added *Strict Mode* to database transactions.
 - Escape behaviour in `where()` clauses has changed; values in those with the “FALSE” argument are no longer escaped (ie: quoted).

- Config
 - Added ‘application/vnd.ms-powerpoint’ to list of mime types.
 - Added ‘audio/mpg’ to list of mime types.
 - Added new user-modifiable file constants.php containing file mode and fopen constants.
 - Added the ability to set CRLF settings via config in the *Email* class.
- Libraries
 - Added increased security for filename handling in the Upload library.
 - Added increased security for sessions for client-side data tampering.
 - The MySQLi forge class is now in sync with MySQL forge.
 - Added the ability to set CRLF settings via config in the *Email* class.
 - *Unit Testing* results are now colour coded, and a change was made to the default template of results.
 - Added a valid_emails rule to the Validation class.
 - The *Zip* class now exits within download().
 - The *Zip* class has undergone a substantial re-write for speed and clarity (thanks stanleyxu for the hard work and code contribution in bug report #3425!)
- Helpers
 - Added a Compatibility Helper for using some common PHP 5 functions safely in applications that might run on PHP 4 servers (thanks Seppo for the hard work and code contribution!)
 - Added form_button() in the *Form helper*.
 - Changed the radio() and checkbox() functions to default to not checked by default.
 - Added the ability to include an optional HTTP Response Code in the redirect() function of the *URL Helper*.
 - Modified img() in the *HTML Helper* to remove an unneeded space (#4208).
 - Modified anchor() in the *URL helper* to no longer add a default title= attribute (#4209).
 - The *Download helper* now exits within force_download().
 - Added get_dir_file_info(), get_file_info(), and get_mime_by_extension() to the *File Helper*.
 - Added symbolic_permissions() and octal_permissions() to the *File helper*.
- Plugins
 - Modified captcha generation to first look for the function imagecreatetruecolor, and fallback to imagecreate if it isn’t available (#4226).
- Other Changes
 - Added ability for xss_clean() to accept arrays.
 - Removed closing PHP tags from all PHP files to avoid accidental output and potential ‘cannot modify headers’ errors.
 - Removed “scripts” from the auto-load search path. Scripts were deprecated in Version 1.4.1 (September 21, 2006). If you still need to use them for legacy reasons, they must now be manually loaded in each Controller.
 - Added a *Reserved Names* page to the userguide, and migrated reserved controller names into it.
 - Added a *Common Functions* page to the userguide for globally available functions.

- Improved security and performance of `xss_clean()`.

Bugfixes for 1.6.2

- Fixed a bug where SET queries were not being handled as “write” queries.
- Fixed a bug (#3191) with ORIG_PATH_INFO URI parsing.
- Fixed a bug in DB Forge, when inserting an id field (#3456).
- Fixed a bug in the table library that could cause identically constructed rows to be dropped (#3459).
- Fixed DB Driver and MySQLi result driver checking for resources instead of objects (#3461).
- Fixed an AR_caching error where it wasn’t tracking table aliases (#3463).
- Fixed a bug in AR compiling, where select statements with arguments got incorrectly escaped (#3478).
- Fixed an incorrect documentation of `$this->load->language` (#3520).
- Fixed bugs (#3523, #4350) in `get_filenames()` with recursion and problems with Windows when `$include_path` is used.
- Fixed a bug (#4153) in the XML-RPC class preventing `dateTime.iso8601` from being used.
- Fixed an AR bug with `or_where_not_in()` (#4171).
- Fixed a bug with `xss_clean()` that would add semicolons to GET URI variable strings.
- Fixed a bug (#4206) in the Directory Helper where the directory resource was not being closed, and minor improvements.
- Fixed a bug in the FTP library where `delete_dir()` was not working recursively (#4215).
- Fixed a Validation bug when `set_rules()` is used with a non-array field name and rule (#4220).
- Fixed a bug (#4223) where DB caching would not work for returned DB objects or multiple DB connections.
- Fixed a bug in the Upload library that might output the same error twice (#4390).
- Fixed an AR bug when joining with a table alias and table prefix (#4400).
- Fixed a bug in the DB class testing the `$params` argument.
- Fixed a bug in the Table library where the integer 0 in cell data would be displayed as a blank cell.
- Fixed a bug in `link_tag()` of the *URL helper* where a key was passed instead of a value.
- Fixed a bug in `DB_result::row()` that prevented it from returning individual fields with MySQL NULL values.
- Fixed a bug where SMTP emails were not having dot transformation performed on lines that begin with a dot.
- Fixed a bug in `display_error()` in the DB driver that was instantiating new Language and Exception objects, and not using the error heading.
- Fixed a bug (#4413) where a URI containing slashes only e.g. `‘http://example.com/index.php?’` would result in PHP errors
- Fixed an array to string conversion error in the Validation library (#4425)
- Fixed bug (#4451, #4299, #4339) where failed transactions will not rollback when debug mode is enabled.
- Fixed a bug (#4506) with `overlay_watermark()` in the Image library preventing support for PNG-24s with alpha transparency
- Fixed assorted user guide typos (#3453, #4364, #4379, #4399, #4408, #4412, #4448, #4488).

10.5.16 Version 1.6.1

Release Date: February 12, 2008 Hg Tag: 1.6.1

- Active Record
 - Added *Active Record Caching*.
 - Made Active Record fully database-prefix aware.
- Database drivers
 - Added support for setting client character set and collation for MySQLi.
- Core Changes
 - Modified `xss_clean()` to be more intelligent with its handling of URL encoded strings.
 - Added `$_SERVER`, `$_FILES`, `$_ENV`, and `$_SESSION` to sanitization of globals.
 - Added a *Path Helper*.
 - Simplified `_reindex_segments()` in the URI class.
 - Escaped the '-' in the default 'permitted_uri_chars' config item, to prevent errors if developers just try to add additional characters to the end of the default expression.
 - Modified method calling to controllers to show a 404 when a private or protected method is accessed via a URL.
 - Modified framework initiated 404s to log the controller and method for invalid requests.
- Helpers
 - Modified `get_filenames()` in the File Helper to return FALSE if the `$source_dir` is not readable.

Bugfixes for 1.6.1

- Deprecated `is_numeric` as a validation rule. Use of `numeric` and `integer` are preferred.
- Fixed bug (#3379) in DBForge with SQLite for table creation.
- Made Active Record fully database prefix aware (#3384).
- Fixed a bug where DBForge was outputting invalid SQL in Postgres by adding brackets around the tables in FROM.
- Changed the behaviour of Active Record's `update()` to make the WHERE clause optional (#3395).
- Fixed a bug (#3396) where certain POST variables would cause a PHP warning.
- Fixed a bug in query binding (#3402).
- Changed order of SQL keywords in the Profiler `$highlight` array so OR would not be highlighted before ORDER BY.
- Fixed a bug (#3404) where the MySQLi driver was testing if `$this->conn_id` was a resource instead of an object.
- Fixed a bug (#3419) connecting to a database via a DSN string.
- Fixed a bug (#3445) where the routed segment array was not re-indexed to begin with 1 when the default controller is used.
- Fixed assorted user guide typos.

10.5.17 Version 1.6.0

Release Date: January 30, 2008

- DBForge
 - Added *DBForge* to the database tools.
 - Moved `create_database()` and `drop_database()` into *DBForge*.
 - Added `add_field()`, `add_key()`, `create_table()`, `drop_table()`, `add_column()`, `drop_column()`, `modify_column()` into *DBForge*.
- Active Record
 - Added `protect_identifiers()` in *Active Record*.
 - All AR queries are backticked if appropriate to the database.
 - Added `where_in()`, `or_where_in()`, `where_not_in()`, `or_where_not_in()`, `not_like()` and `or_not_like()` to *Active Record*.
 - Added support for `limit()` into `update()` and `delete()` statements in *Active Record*.
 - Added `empty_table()` and `truncate_table()` to *Active Record*.
 - Added the ability to pass an array of tables to the `delete()` statement in *Active Record*.
 - Added `count_all_results()` function to *Active Record*.
 - Added `select_max()`, `select_min()`, `select_avg()` and `select_sum()` to *Active Record*.
 - Added the ability to use aliases with joins in *Active Record*.
 - Added a third parameter to Active Record's `like()` clause to control where the wildcard goes.
 - Added a third parameter to `set()` in *Active Record* that withholds escaping data.
 - Changed the behaviour of variables submitted to the `where()` clause with no values to auto set "IS NULL"
- Other Database Related
 - MySQL driver now requires MySQL 4.1+
 - Added `$this->DB->save_queries` variable to DB driver, enabling queries to get saved or not. Previously they were always saved.
 - Added `$this->db->dbprefix()` to manually add database prefixes.
 - Added 'random' as an `order_by()` option, and removed "rand()" as a listed option as it was MySQL only.
 - Added a check for NULL fields in the MySQL database backup utility.
 - Added "constrain_by_prefix" parameter to `db->list_table()` function. If set to TRUE it will limit the result to only table names with the current prefix.
 - Deprecated from Active Record; `getwhere()` for `get_where()`; `groupby()` for `group_by()`; `havingor()` for `having_or()`; `orderby()` for `order_by()`; `orwhere()` for `or_where()`; and `orlike()` for `or_like()`.
 - Modified `csv_from_result()` to output CSV data more in the spirit of basic rules of RFC 4180.
 - Added 'char_set' and 'dbcollat' database configuration settings, to explicitly set the client communication properly.
 - Removed 'active_r' configuration setting and replaced with a global `$active_record` setting, which is more in harmony with the global nature of the behavior (#1834).
- Core changes

- Added ability to load multiple views, whose content will be appended to the output in the order loaded.
- Added the ability to *auto-load Models*.
- Reorganized the URI and Routes classes for better clarity.
- Added Compat.php to allow function overrides for older versions of PHP or PHP environments missing certain extensions / libraries
- Added memory usage, GET, URI string data, and individual query execution time to Profiler output.
- Deprecated Scaffolding.
- Added is_really_writable() to Common.php to provide a cross-platform reliable method of testing file/folder writability.

- Libraries

- Changed the load protocol of Models to allow for extension.
- Strengthened the Encryption library to help protect against man in the middle attacks when MCRYPT_MODE_CBC mode is used.
- Added Flashdata variables, session_id regeneration and configurable session update times to the *Session class*.
- Removed ‘last_visit’ from the Session class.
- Added a language entry for valid_ip validation error.
- Modified prep_for_form() in the Validation class to accept arrays, adding support for POST array validation (via callbacks only)
- Added an “integer” rule into the Validation library.
- Added valid_base64() to the Validation library.
- Documented clear() in the *Image Processing* library.
- Changed the behaviour of custom callbacks so that they no longer trigger the “required” rule.
- Modified Upload class \$_FILES error messages to be more precise.
- Moved the safe mode and auth checks for the Email library into the constructor.
- Modified variable names in _ci_load() method of Loader class to avoid conflicts with view variables.
- Added a few additional mime type variations for CSV.
- Enabled the ‘system’ methods for the XML-RPC Server library, except for ‘system.multicall’ which is still disabled.

- Helpers & Plugins

- Added link_tag() to the *HTML helper*.
- Added img() to the *HTML helper*.
- Added ability to “extend” *Helpers*.
- Added an *email helper* into core helpers.
- Added strip_quotes() function to *string helper*.
- Added reduce_multiples() function to *string helper*.
- Added quotes_to_entities() function to *string helper*.
- Added form_fieldset(), form_fieldset_close(), form_label(), and form_reset() function to *form helper*.

- Added support for external urls in `form_open()`.
- Removed support for `db_backup` in MySQLi due to incompatible functions.
- Javascript Calendar plugin now uses the months and days from the calendar language file, instead of hard-coded values, internationalizing it.
- Documentation Changes
 - Added Writing Documentation section for the community to use in writing their own documentation.
 - Added titles to all user manual pages.
 - Added attributes into `<html>` of `userguide` for valid html.
 - Added *Zip Encoding Class* to the table of contents of the `userguide`.
 - Moved part of the `userguide` menu javascript to an external file.
 - Documented `distinct()` in *Active Record*.
 - Documented the `timezones()` function in the *Date Helper*.
 - Documented `unset_userdata` in the *Session class*.
 - Documented 2 config options to the *Database configuration* page.

Bug fixes for Version 1.6.0

- Fixed a bug (#1813) preventing using `$CI->db` in the same application with returned database objects.
- Fixed a bug (#1842) where the `$this->uri->rsegments` array would not include the ‘index’ method if routed to the controller without an implicit method.
- Fixed a bug (#1872) where `word_limiter()` was not retaining whitespace.
- Fixed a bug (#1890) in `csv_from_result()` where content that included the delimiter would break the file.
- Fixed a bug (#2542) in the `clean_email()` method of the `Email` class to allow for non-numeric / non-sequential array keys.
- Fixed a bug (#2545) in `_html_entity_decode_callback()` when ‘global_xss_filtering’ is enabled.
- Fixed a bug (#2668) in the *parser class* where numeric data was ignored.
- Fixed a bug (#2679) where the “previous” pagination link would get drawn on the first page.
- Fixed a bug (#2702) in `_object_to_array` that broke some types of inserts and updates.
- Fixed a bug (#2732) in the SQLite driver for PHP 4.
- Fixed a bug (#2754) in `Pagination` to scan for non-positive `num_links`.
- Fixed a bug (#2762) in the *Session library* where user agent matching would fail on user agents ending with a space.
- Fixed a bug (#2784) `$field_names[]` vs `$Ffield_names[]` in postgres and sqlite drivers.
- Fixed a bug (#2810) in the *typography helper* causing extraneous paragraph tags when string contains tags.
- Fixed a bug (#2849) where arguments passed to a subfolder controller method would be incorrectly shifted, dropping the 3rd segment value.
- Fixed a bug (#2858) which referenced a wrong variable in the `Image` class.
- Fixed a bug (#2875) when loading plugin files as `_plugin`. and not `_pi`.
- Fixed a bug (#2912) in `get_filenames()` in the *File Helper* where the array wasn’t cleared after each call.

- Fixed a bug (#2974) in `highlight_phrase()` that caused an error with slashes.
- Fixed a bug (#3003) in the Encryption Library to support modes other than `MCRYPT_MODE_ECB`
- Fixed a bug (#3015) in the *User Agent library* where more than 2 languages were not reported with `languages()`.
- Fixed a bug (#3017) in the *Email library* where some timezones were calculated incorrectly.
- Fixed a bug (#3024) in which `master_dim` wasn't getting reset by `clear()` in the Image library.
- Fixed a bug (#3156) in Text Helper `highlight_code()` causing PHP tags to be handled incorrectly.
- Fixed a bug (#3166) that prevented `num_rows` from working in Oracle.
- Fixed a bug (#3175) preventing certain libraries from working properly when autoloaded in PHP 4.
- Fixed a bug (#3267) in the Typography Helper where unordered list was listed "un.
- Fixed a bug (#3268) where the Router could leave '/' as the path.
- Fixed a bug (#3279) where the Email class was sending the wrong Content-Transfer-Encoding for some character sets.
- Fixed a bug (#3284) where the `rsegment` array would not be set properly if the requested URI contained more segments than the routed URI.
- Removed extraneous load of `$CFG` in `_display_cache()` of the Output class (#3285).
- Removed an extraneous call to loading models (#3286).
- Fixed a bug (#3310) with sanitization of globals in the Input class that could unset CI's global variables.
- Fixed a bug (#3314) which would cause the top level path to be deleted in `delete_files()` of the File helper.
- Fixed a bug (#3328) where the smiley helper might return an undefined variable.
- Fixed a bug (#3330) in the FTP class where a comparison wasn't getting made.
- Removed an unused parameter from Profiler (#3332).
- Fixed a bug in database driver where `num_rows` property wasn't getting updated.
- Fixed a bug in the *upload library* when `allowed_files` wasn't defined.
- Fixed a bug in `word_wrap()` of the Text Helper that incorrectly referenced an object.
- Fixed a bug in Validation where `valid_ip()` wasn't called properly.
- Fixed a bug in Validation where individual error messages for checkboxes wasn't supported.
- Fixed a bug in captcha calling an invalid PHP function.
- Fixed a bug in the cookie helper "set_cookie" function. It was not honoring the config settings.
- Fixed a bug that was making validation callbacks required even when not set as such.
- Fixed a bug in the XML-RPC library so if a type is specified, a more intelligent decision is made as to the default type.
- Fixed an example of comma-separated emails in the email library documentation.
- Fixed an example in the Calendar library for Showing Next/Previous Month Links.
- Fixed a typo in the database language file.
- Fixed a typo in the image language file "suppor" to "support".
- Fixed an example for XML RPC.
- Fixed an example of `accept_charset()` in the *User Agent Library*.

- Fixed a typo in the docblock comments that had CodeIgniter spelled CodeIgnitor.
- Fixed a typo in the *String Helper* (uniquid changed to unidid).
- Fixed typos in the email Language class (email_attachment_unredable, email_filed_smtp_login), and FTP Class (ftp_unable_to_rename).
- Added a stripslashes() into the Upload Library.
- Fixed a series of grammatical and spelling errors in the language files.
- Fixed assorted user guide typos.

10.5.18 Version 1.5.4

Release Date: July 12, 2007

- Added *custom Language files* to the *autoload* options.
- Added stripslashes() to the _clean_input_data() function in the *Input class* when magic quotes is on so that data will always be un-slashed within the framework.
- Added array to string into the *profiler*.
- Added some additional mime types in application/config/mimes.php.
- Added filename_security() method to *Input library*.
- Added some additional arguments to the *Inflection helper* singular() to compensate for words ending in “s”. Also added a force parameter to pluralize().
- Added \$config['charset'] to the config file. Default value is ‘UTF-8’, used in some string handling functions.
- Fixed MSSQL insert_id().
- Fixed a logic error in the DB trans_status() function. It was incorrectly returning TRUE on failure and FALSE on success.
- Fixed a bug that was allowing multiple load attempts on extended classes.
- Fixed a bug in the bootstrap file that was incorrectly attempting to discern the full server path even when it was explicitly set by the user.
- Fixed a bug in the escape_str() function in the MySQL driver.
- Fixed a typo in the *Calendar library*
- Fixed a typo in rpcs.php library
- Fixed a bug in the *Zip library*, providing PC Zip file compatibility with Mac OS X
- Fixed a bug in router that was ignoring the scaffolding route for optimization
- Fixed an IP validation bug.
- Fixed a bug in display of POST keys in the *Profiler* output
- Fixed a bug in display of queries with characters that would be interpreted as HTML in the *Profiler* output
- Fixed a bug in display of Email class print debugger with characters that would be interpreted as HTML in the debugging output
- Fixed a bug in the Content-Transfer-Encoding of HTML emails with the quoted-printable MIME type
- Fixed a bug where one could unset certain PHP superglobals by setting them via GET or POST data
- Fixed an undefined function error in the insert_id() function of the PostgreSQL driver

- Fixed various doc typos.
- Documented two functions from the *String helper* that were missing from the user guide: `trim_slashes()` and `reduce_double_slashes()`.
- Docs now validate to XHTML 1 transitional
- Updated the XSS Filtering to take into account the IE `expression()` ability and improved certain deletions to prevent possible exploits
- Modified the Router so that when Query Strings are Enabled, the controller trigger and function trigger values are sanitized for filename include security.
- Modified the `is_image()` method in the Upload library to take into account Windows IE 6/7 eccentricities when dealing with MIMEs
- Modified XSS Cleaning routine to be more performance friendly and compatible with PHP 5.2's new PCRE backtrack and recursion limits.
- Modified the *URL Helper* to type cast the `$title` as a string in case a numeric value is supplied
- Modified Form Helper `form_dropdown()` to type cast the keys and values of the options array as strings, allowing numeric values to be properly set as 'selected'
- Deprecated the use of `is_numeric()` in various places since it allows periods. Due to compatibility problems with `ctype_digit()`, making it unreliable in some installations, the following regular expression was used instead: `preg_match("/^[0-9]/", $n)`
- Deprecated: APPVER has been deprecated and replaced with CI_VERSION for clarity.

10.5.19 Version 1.5.3

Release Date: April 15, 2007

- Added array to string into the profiler
- Code Igniter references updated to CodeIgniter
- pMachine references updated to EllisLab
- Fixed a bug in the repeater function of *string helper*.
- Fixed a bug in ODBC driver
- Fixed a bug in `result_array()` that was returning an empty array when no result is produced.
- Fixed a bug in the redirect function of the *url helper*.
- Fixed an undefined variable in Loader
- Fixed a version bug in the Postgres driver
- Fixed a bug in the textarea function of the form helper for use with strings
- Fixed doc typos.

10.5.20 Version 1.5.2

Release Date: February 13, 2007

- Added subversion information to the *downloads* page.
- Added support for captions in the *Table Library*

- Fixed a bug in the *download_helper* that was causing Internet Explorer to load rather than download
- Fixed a bug in the Active Record Join function that was not taking table prefixes into consideration.
- Removed unescaped variables in error messages of Input and Router classes
- Fixed a bug in the Loader that was causing errors on Libraries loaded twice. A debug message is now silently made in the log.
- Fixed a bug in the *form_helper* that gave textarea a value attribute
- Fixed a bug in the *Image Library* that was ignoring resizing the same size image
- Fixed some doc typos.

10.5.21 Version 1.5.1

Release Date: November 23, 2006

- Added support for submitting arrays of libraries in the `$this->load->library` function.
- Added support for naming custom library files in lower or uppercase.
- Fixed a bug related to output buffering.
- Fixed a bug in the active record class that was not resetting query data after a completed query.
- Fixed a bug that was suppressing errors in controllers.
- Fixed a problem that can cause a loop to occur when the config file is missing.
- Fixed a bug that occurred when multiple models were loaded with the third parameter set to TRUE.
- Fixed an oversight that was not unsetting globals properly in the input sanitize function.
- Fixed some bugs in the Oracle DB driver.
- Fixed an incorrectly named variable in the MySQLi result driver.
- Fixed some doc typos.

10.5.22 Version 1.5.0.1

Release Date: October 31, 2006

- Fixed a problem in which duplicate attempts to load helpers and classes were not being stopped.
- Fixed a bug in the `word_wrap()` helper function.
- Fixed an invalid color Hex number in the Profiler class.
- Fixed a corrupted image in the user guide.

10.5.23 Version 1.5.0

Release Date: October 30, 2006

- Added *DB utility class*, permitting DB backups, CVS or XML files from DB results, and various other functions.
- Added *Database Caching Class*.
- Added *transaction support* to the database classes.

- Added *Profiler Class* which generates a report of Benchmark execution times, queries, and POST data at the bottom of your pages.
- Added *User Agent Library* which allows browsers, robots, and mobile devices to be identified.
- Added *HTML Table Class* , enabling tables to be generated from arrays or database results.
- Added *Zip Encoding Library*.
- Added *FTP Library*.
- Added the ability to *extend libraries* and *extend core classes*, in addition to being able to replace them.
- Added support for storing *models within sub-folders*.
- Added *Download Helper*.
- Added *simple_query()* function to the database classes
- Added *standard_date()* function to the Date Helper.
- Added *\$query->free_result()* to database class.
- Added *\$query->list_fields()* function to database class
- Added *\$this->db->platform()* function
- Added new *File Helper*: *get_filenames()*
- Added new helper: *Smiley Helper*
- Added support for ** and ** lists in the *HTML Helper*
- Added the ability to rewrite *short tags* on-the-fly, converting them to standard PHP statements, for those servers that do not support short tags. This allows the cleaner syntax to be used regardless of whether it's supported by the server.
- Added the ability to *rename or relocate the "application" folder*.
- Added more thorough initialization in the upload class so that all class variables are reset.
- Added "is_numeric" to validation, which uses the native PHP is_numeric function.
- Improved the URI handler to make it more reliable when the \$config['uri_protocol'] item is set to AUTO.
- Moved most of the functions in the Controller class into the Loader class, allowing fewer reserved function names for controllers when running under PHP 5.
- Updated the DB Result class to return an empty array when \$query->result() doesn't produce a result.
- Updated the input->cookie() and input->post() functions in *Input Class* to permit arrays contained cookies that are arrays to be run through the XSS filter.
- Documented three functions from the Validation class that were missing from the user guide: set_select(), set_radio(), and set_checkbox().
- Fixed a bug in the Email class related to SMTP Helo data.
- Fixed a bug in the word wrapping helper and function in the email class.
- Fixed a bug in the validation class.
- Fixed a bug in the typography helper that was incorrectly wrapping block level elements in paragraph tags.
- Fixed a problem in the form_prep() function that was double encoding entities.
- Fixed a bug that affects some versions of PHP when output buffering is nested.

- Fixed a bug that caused CI to stop working when the PHP magic `__get()` or `__set()` functions were used within models or controllers.
- Fixed a pagination bug that was permitting negative values in the URL.
- Fixed an oversight in which the Loader class was not allowed to be extended.
- Changed `_get_config()` to `get_config()` since the function is not a private one.
- **Deprecated “init” folder.** Initialization happens automatically now. *Please see documentation.*
- **Deprecated** `$this->db->field_names()` USE `$this->db->list_fields()`
- **Deprecated** the `$config['log_errors']` item from the `config.php` file. Instead, `$config['log_threshold']` can be set to “0” to turn it off.

10.5.24 Version 1.4.1

Release Date: September 21, 2006

- Added a new feature that passes URI segments directly to your function calls as parameters. See the *Controllers* page for more info.
- Added support for a function named `_output()`, which when used in your controllers will received the final rendered output from the output class. More info in the *Controllers* page.
- Added several new functions in the *URI Class* to let you retrieve and manipulate URI segments that have been re-routed using the *URI Routing* feature. Previously, the URI class did not permit you to access any re-routed URI segments, but now it does.
- Added `$this->output->set_header()` function, which allows you to set server headers.
- Updated plugins, helpers, and language classes to allow your application folder to contain its own plugins, helpers, and language folders. Previously they were always treated as global for your entire installation. If your application folder contains any of these resources they will be used *instead* the global ones.
- Added *Inflector helper*.
- Added `element()` function in the *array helper*.
- Added `RAND()` to `active_record_orderby()` function.
- Added `delete_cookie()` and `get_cookie()` to *Cookie helper*, even though the input class has a cookie fetching function.
- Added Oracle database driver (still undergoing testing so it might have some bugs).
- Added the ability to combine pseudo-variables and php variables in the template parser class.
- Added output compression option to the config file.
- Removed the `is_numeric` test from the `db->escape()` function.
- Fixed a MySQLi bug that was causing error messages not to contain proper error data.
- Fixed a bug in the email class which was causing it to ignore explicitly set alternative headers.
- Fixed a bug that was causing a PHP error when the Exceptions class was called within the `get_config()` function since it was causing problems.
- Fixed an oversight in the cookie helper in which the config file cookie settings were not being honored.
- Fixed an oversight in the upload class. An item mentioned in the 1.4 changelog was missing.
- Added some code to allow email attachments to be reset when sending batches of email.

- Deprecated the application/scripts folder. It will continue to work for legacy users, but it is recommended that you create your own *libraries* or *models* instead. It was originally added before CI had user libraries or models, but it's not needed anymore.
- Deprecated the \$autoload['core'] item from the autoload.php file. Instead, please now use: \$autoload['libraries']
- Deprecated the following database functions: \$this->db->smart_escape_str() and \$this->db->fields().

10.5.25 Version 1.4.0

Release Date: September 17, 2006

- Added *Hooks* feature, enabling you to tap into and modify the inner workings of the framework without hacking the core files.
- Added the ability to organize controller files *into sub-folders*. Kudos to Marco for [suggesting](#) this (and the next two) feature.
- Added regular expressions support for *routing rules*.
- Added the ability to *remap function calls* within your controllers.
- Added the ability to *replace core system classes* with your own classes.
- Added support for % character in URL.
- Added the ability to supply full URLs using the *anchor()* helper function.
- Added mode parameter to *file_write()* helper.
- Added support for changing the port number in the *Postgres driver*.
- Moved the list of “allowed URI characters” out of the Router class and into the config file.
- Moved the MIME type array out of the Upload class and into its own file in the application/config/ folder.
- Updated the Upload class to allow the upload field name to be set when calling *do_upload()*.
- Updated the *Config Library* to be able to load config files silently, and to be able to assign config files to their own index (to avoid collisions if you use multiple config files).
- Updated the URI Protocol code to allow more options so that URLs will work more reliably in different environments.
- Updated the form_open() helper to allow the GET method to be used.
- Updated the MySQLi execute() function with some code to help prevent lost connection errors.
- Updated the SQLite Driver to check for object support before attempting to return results as objects. If unsupported it returns an array.
- Updated the Models loader function to allow multiple loads of the same model.
- Updated the MS SQL driver so that single quotes are escaped.
- Updated the Postgres and ODBC drivers for better compatibility.
- Removed a strtolower() call that was changing URL segments to lower case.
- Removed some references that were interfering with PHP 4.4.1 compatibility.
- Removed backticks from Postgres class since these are not needed.
- Renamed display() to _display() in the Output class to make it clear that it's a private function.
- Deprecated the hash() function due to a naming conflict with a native PHP function with the same name. Please use dohash() instead.

- Fixed an bug that was preventing the input class from unsetting GET variables.
- Fixed a router bug that was making it too greedy when matching end segments.
- Fixed a bug that was preventing multiple discrete database calls.
- Fixed a bug in which loading a language file was producing a “file contains no data” message.
- Fixed a session bug caused by the XSS Filtering feature inadvertently changing the case of certain words.
- Fixed some missing prefixes when using the database prefix feature.
- Fixed a typo in the Calendar class (cal_november).
- Fixed a bug in the form_checkbox() helper.
- Fixed a bug that was allowing the second segment of the URI to be identical to the class name.
- Fixed an evaluation bug in the database initialization function.
- Fixed a minor bug in one of the error messages in the language class.
- Fixed a bug in the date helper timespan function.
- Fixed an undefined variable in the DB Driver class.
- Fixed a bug in which dollar signs used as binding replacement values in the DB class would be treated as RegEx back-references.
- Fixed a bug in the set_hash() function which was preventing MD5 from being used.
- Fixed a couple bugs in the Unit Testing class.
- Fixed an incorrectly named variable in the Validation class.
- Fixed an incorrectly named variable in the URI class.
- Fixed a bug in the config class that was preventing the base URL from being called properly.
- Fixed a bug in the validation class that was not permitting callbacks if the form field was empty.
- Fixed a problem that was preventing scaffolding from working properly with MySQLi.
- Fixed some MS SQL bugs.
- Fixed some doc typos.

10.5.26 Version 1.3.3

Release Date: June 1, 2006

- Models do **not** connect automatically to the database as of this version. *More info here.*
- Updated the Sessions class to utilize the active record class when running session related queries. Previously the queries assumed MySQL syntax.
- Updated alternator() function to re-initialize when called with no arguments, allowing multiple calls.
- Fixed a bug in the active record “having” function.
- Fixed a problem in the validation class which was making checkboxes be ignored when required.
- Fixed a bug in the word_limiter() helper function. It was cutting off the fist word.
- Fixed a bug in the xss_clean function due to a PHP bug that affects some versions of html_entity_decode.
- Fixed a validation bug that was preventing rules from being set twice in one controller.
- Fixed a calendar bug that was not letting it use dynamically loaded languages.

- Fixed a bug in the active record class when using WHERE clauses with LIKE
- Fixed a bug in the hash() security helper.
- Fixed some typos.

10.5.27 Version 1.3.2

Release Date: April 17, 2006

- Changed the behavior of the validation class such that if a “required” rule is NOT explicitly stated for a field then all other tests get ignored.
- Fixed a bug in the Controller class that was causing it to look in the local “init” folder instead of the main system one.
- Fixed a bug in the init_pagination file. The \$config item was not being set correctly.
- Fixed a bug in the auto typography helper that was causing inconsistent behavior.
- Fixed a couple bugs in the Model class.
- Fixed some documentation typos and errata.

10.5.28 Version 1.3.1

Release Date: April 11, 2006

- Added a *Unit Testing Library*.
- Added the ability to pass objects to the **insert()** and **update()** database functions. This feature enables you to (among other things) use your *Model class* variables to run queries with. See the Models page for details.
- Added the ability to pass objects to the *view loading function*: `$this->load->view('my_view', $object);`
- Added `getwhere` function to *Active Record class*.
- Added `count_all` function to *Active Record class*.
- Added language file for scaffolding and fixed a scaffolding bug that occurs when there are no rows in the specified table.
- Added `$this->db->last_query()`, which allows you to view your last query that was run.
- Added a new mime type to the upload class for better compatibility.
- Changed how cache files are read to prevent PHP errors if the cache file contains an XML tag, which PHP wants to interpret as a short tag.
- Fixed a bug in a couple of the active record functions (where and orderby).
- Fixed a bug in the image library when `realpath()` returns false.
- Fixed a bug in the Models that was preventing libraries from being used within them.
- Fixed a bug in the “exact_length” function of the validation class.
- Fixed some typos in the user guide

10.5.29 Version 1.3

Release Date: April 3, 2006

- Added support for *Models*.
- Redesigned the database libraries to support additional RDBMs (Postgres, MySQLi, etc.).
- Redesigned the *Active Record* class to enable more varied types of queries with simpler syntax, and advanced features like JOINS.
- Added a feature to the database class that lets you run *custom function calls*.
- Added support for *private functions* in your controllers. Any controller function name that starts with an underscore will not be served by a URI request.
- Added the ability to pass your own initialization parameters to your *custom core libraries* when using `$this->load->library()`
- Added support for running standard *query string URLs*. These can be optionally enabled in your config file.
- Added the ability to *specify a “suffix”*, which will be appended to your URLs. For example, you could add `.html` to your URLs, making them appear static. This feature is enabled in your config file.
- Added a new error template for use with native PHP errors.
- Added “alternator” function in the *string helpers*.
- Removed slashing from the input class. After much debate we decided to kill this feature.
- Change the commenting style in the scripts to the PEAR standard so that IDEs and tools like phpDocumenter can harvest the comments.
- Added better class and function name-spacing to avoid collisions with user developed classes. All CodeIgniter classes are now prefixed with `CI_` and all controller methods are prefixed with `_ci` to avoid controller collisions. A list of reserved function names can be *found here*.
- Redesigned how the “CI” super object is referenced, depending on whether PHP 4 or 5 is being run, since PHP 5 allows a more graceful way to manage objects that utilizes a bit less resources.
- Deprecated: `$this->db->use_table()` has been deprecated. Please read the *Active Record* page for information.
- Deprecated: `$this->db->smart_escape_str()` has been deprecated. Please use this instead: `$this->db->escape()`
- Fixed a bug in the exception handler which was preventing some PHP errors from showing up.
- Fixed a typo in the URI class. `$this->total_segment()` should be plural: `$this->total_segments()`
- Fixed some typos in the default calendar template
- Fixed some typos in the user guide

10.5.30 Version 1.2

Release Date: March 21, 2006

- Redesigned some internal aspects of the framework to resolve scoping problems that surfaced during the beta tests. The problem was most notable when instantiating classes in your constructors, particularly if those classes in turn did work in their constructors.
- Added a global function named `get_instance()` allowing the main CodeIgniter object to be accessible throughout your own classes.
- Added new *File Helper*: `delete_files()`

- Added new *URL Helpers*: `base_url()`, `index_page()`
- Added the ability to create your own *core libraries* and store them in your local application directory.
- Added an overwrite option to the *Upload class*, enabling files to be overwritten rather than having the file name appended.
- Added Javascript Calendar plugin.
- Added search feature to user guide. Note: This is done using Google, which at the time of this writing has not crawled all the pages of the docs.
- Updated the parser class so that it allows tag pars within other tag pairs.
- Fixed a bug in the DB “where” function.
- Fixed a bug that was preventing custom config files to be auto-loaded.
- Fixed a bug in the mysql class bind feature that prevented question marks in the replacement data.
- Fixed some bugs in the `xss_clean` function

10.5.31 Version Beta 1.1

Release Date: March 10, 2006

- Added a *Calendaring class*.
- Added support for running *multiple applications* that share a common CodeIgniter backend.
- Moved the “uri protocol” variable from the `index.php` file into the `config.php` file
- Fixed a problem that was preventing certain function calls from working within constructors.
- Fixed a problem that was preventing the `$this->load->library` function from working in constructors.
- Fixed a bug that occurred when the session class was loaded using the auto-load routine.
- Fixed a bug that can happen with PHP versions that do not support the `E_STRICT` constant
- Fixed a data type error in the `form_radio` function (form helper)
- Fixed a bug that was preventing the `xss_clean` function from being called from the validation class.
- Fixed the cookie related config names, which were incorrectly specified as `$conf` rather than `$config`
- Fixed a pagination problem in the scaffolding.
- Fixed a bug in the mysql class “where” function.
- Fixed a regex problem in some code that trimmed duplicate slashes.
- Fixed a bug in the `br()` function in the HTML helper
- Fixed a syntax mistake in the `form_dropdown` function in the Form Helper.
- Removed the “style” attributes from the form helpers.
- Updated the documentation. Added “next/previous” links to each page and fixed various typos.

10.5.32 Version Beta 1.0

Release Date: February 28, 2006

First publicly released version.

10.6 Open Software License (“OSL”) v 3.0

This Open Software License (the “License”) applies to any original work of authorship (the “Original Work”) whose owner (the “Licensor”) has placed the following licensing notice adjacent to the copyright notice for the Original Work:

Licensed under the Open Software License version 3.0

10.6.1 1) Grant of Copyright License

Licensor grants You a worldwide, royalty-free, non-exclusive, sublicensable license, for the duration of the copyright, to do the following:

- a) to reproduce the Original Work in copies, either alone or as part of a collective work;
- b) to translate, adapt, alter, transform, modify, or arrange the Original Work, thereby creating derivative works (“Derivative Works”) based upon the Original Work;
- c) to distribute or communicate copies of the Original Work and Derivative Works to the public, *with the proviso that copies of Original Work or Derivative Works that You distribute or communicate shall be licensed under this Open Software License*;
- d) to perform the Original Work publicly; and
- e) to display the Original Work publicly.

10.6.2 2) Grant of Patent License

Licensor grants You a worldwide, royalty-free, non-exclusive, sublicensable license, under patent claims owned or controlled by the Licensor that are embodied in the Original Work as furnished by the Licensor, for the duration of the patents, to make, use, sell, offer for sale, have made, and import the Original Work and Derivative Works.

10.6.3 3) Grant of Source Code License

The term “Source Code” means the preferred form of the Original Work for making modifications to it and all available documentation describing how to modify the Original Work. Licensor agrees to provide a machine-readable copy of the Source Code of the Original Work along with each copy of the Original Work that Licensor distributes. Licensor reserves the right to satisfy this obligation by placing a machine-readable copy of the Source Code in an information repository reasonably calculated to permit inexpensive and convenient access by You for as long as Licensor continues to distribute the Original Work.

10.6.4 4) Exclusions From License Grant

Neither the names of Licensor, nor the names of any contributors to the Original Work, nor any of their trademarks or service marks, may be used to endorse or promote products derived from this Original Work without express prior permission of the Licensor. Except as expressly stated herein, nothing in this License grants any license to Licensor’s trademarks, copyrights, patents, trade secrets or any other intellectual property. No patent license is granted to make, use, sell, offer for sale, have made, or import embodiments of any patent claims other than the licensed claims defined in Section 2) No license is granted to the trademarks of Licensor even if such marks are included in the Original Work. Nothing in this License shall be interpreted to prohibit Licensor from licensing under terms different from this License any Original Work that Licensor otherwise would have a right to license.

10.6.5 5) External Deployment

The term “External Deployment” means the use, distribution, or communication of the Original Work or Derivative Works in any way such that the Original Work or Derivative Works may be used by anyone other than You, whether those works are distributed or communicated to those persons or made available as an application intended for use over a network. As an express condition for the grants of license hereunder, You must treat any External Deployment by You of the Original Work or a Derivative Work as a distribution under section 1(c).

10.6.6 6) Attribution Rights

You must retain, in the Source Code of any Derivative Works that You create, all copyright, patent, or trademark notices from the Source Code of the Original Work, as well as any notices of licensing and any descriptive text identified therein as an “Attribution Notice.” You must cause the Source Code for any Derivative Works that You create to carry a prominent Attribution Notice reasonably calculated to inform recipients that You have modified the Original Work.

10.6.7 7) Warranty of Provenance and Disclaimer of Warranty

Licensor warrants that the copyright in and to the Original Work and the patent rights granted herein by Licensor are owned by the Licensor or are sublicensed to You under the terms of this License with the permission of the contributor(s) of those copyrights and patent rights. Except as expressly stated in the immediately preceding sentence, the Original Work is provided under this License on an “AS IS” BASIS and WITHOUT WARRANTY, either express or implied, including, without limitation, the warranties of non-infringement, merchantability or fitness for a particular purpose. THE ENTIRE RISK AS TO THE QUALITY OF THE ORIGINAL WORK IS WITH YOU. This DISCLAIMER OF WARRANTY constitutes an essential part of this License. No license to the Original Work is granted by this License except under this disclaimer.

10.6.8 8) Limitation of Liability

Under no circumstances and under no legal theory, whether in tort (including negligence), contract, or otherwise, shall the Licensor be liable to anyone for any indirect, special, incidental, or consequential damages of any character arising as a result of this License or the use of the Original Work including, without limitation, damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses. This limitation of liability shall not apply to the extent applicable law prohibits such limitation.

10.6.9 9) Acceptance and Termination

If, at any time, You expressly assented to this License, that assent indicates your clear and irrevocable acceptance of this License and all of its terms and conditions. If You distribute or communicate copies of the Original Work or a Derivative Work, You must make a reasonable effort under the circumstances to obtain the express assent of recipients to the terms of this License. This License conditions your rights to undertake the activities listed in Section 1, including your right to create Derivative Works based upon the Original Work, and doing so without honoring these terms and conditions is prohibited by copyright law and international treaty. Nothing in this License is intended to affect copyright exceptions and limitations (including “fair use” or “fair dealing”). This License shall terminate immediately and You may no longer exercise any of the rights granted to You by this License upon your failure to honor the conditions in Section 1(c).

10.6.10 10) Termination for Patent Action

This License shall terminate automatically and You may no longer exercise any of the rights granted to You by this License as of the date You commence an action, including a cross-claim or counterclaim, against Licensor or any licensee alleging that the Original Work infringes a patent. This termination provision shall not apply for an action alleging patent infringement by combinations of the Original Work with other software or hardware.

10.6.11 11) Jurisdiction, Venue and Governing Law

Any action or suit relating to this License may be brought only in the courts of a jurisdiction wherein the Licensor resides or in which Licensor conducts its primary business, and under the laws of that jurisdiction excluding its conflict-of-law provisions. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any use of the Original Work outside the scope of this License or after its termination shall be subject to the requirements and penalties of copyright or patent law in the appropriate jurisdiction. This section shall survive the termination of this License.

10.6.12 12) Attorneys' Fees

In any action to enforce the terms of this License or seeking damages relating thereto, the prevailing party shall be entitled to recover its costs and expenses, including, without limitation, reasonable attorneys' fees and costs incurred in connection with such action, including any appeal of such action. This section shall survive the termination of this License.

10.6.13 13) Miscellaneous

If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable.

10.6.14 14) Definition of "You" in This License

"You" throughout this License, whether in upper or lower case, means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity that controls, is controlled by, or is under common control with you. For purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

10.6.15 15) Right to Use

You may use the Original Work in all ways not otherwise restricted or conditioned by this License or by law, and Licensor promises not to interfere with or be responsible for such uses by You.

10.6.16 16) Modification of This License

This License is Copyright © 2005 Lawrence Rosen. Permission is granted to copy, distribute, or communicate this License without modification. Nothing in this License permits You to modify this License as applied to the Original Work or to Derivative Works. However, You may modify the text of this License and copy, distribute or communicate your modified version (the "Modified License") and apply it to other original works of authorship subject to the following conditions: (i) You may not indicate in any way that your Modified License is the "Open Software License" or "OSL" and you may not use those names in the name of your Modified License; (ii) You must replace the notice

specified in the first paragraph above with the notice “Licensed under <insert your license name here>” or with a notice of your own that is not confusingly similar to the notice in this License; and (iii) You may not claim that your original works are open source software unless your Modified License has been approved by Open Source Initiative (OSI) and You comply with its license review and certification process.

10.7 Academic Free License (“AFL”) v 3.0

This Academic Free License (the “License”) applies to any original work of authorship (the “Original Work”) whose owner (the “Licensor”) has placed the following licensing notice adjacent to the copyright notice for the Original Work:

Licensed under the Academic Free License version 3.0

10.7.1 1) Grant of Copyright License

Licensor grants You a worldwide, royalty-free, non-exclusive, sublicensable license, for the duration of the copyright, to do the following:

- a) to reproduce the Original Work in copies, either alone or as part of a collective work;
- b) to translate, adapt, alter, transform, modify, or arrange the Original Work, thereby creating derivative works (“Derivative Works”) based upon the Original Work;
- c) to distribute or communicate copies of the Original Work and Derivative Works to the public, *under any license of your choice that does not contradict the terms and conditions, including Licensor’s reserved rights and remedies, in this Academic Free License*;
- d) to perform the Original Work publicly; and
- e) to display the Original Work publicly.

10.7.2 2) Grant of Patent License

Licensor grants You a worldwide, royalty-free, non-exclusive, sublicensable license, under patent claims owned or controlled by the Licensor that are embodied in the Original Work as furnished by the Licensor, for the duration of the patents, to make, use, sell, offer for sale, have made, and import the Original Work and Derivative Works.

10.7.3 3) Grant of Source Code License

The term “Source Code” means the preferred form of the Original Work for making modifications to it and all available documentation describing how to modify the Original Work. Licensor agrees to provide a machine-readable copy of the Source Code of the Original Work along with each copy of the Original Work that Licensor distributes. Licensor reserves the right to satisfy this obligation by placing a machine-readable copy of the Source Code in an information repository reasonably calculated to permit inexpensive and convenient access by You for as long as Licensor continues to distribute the Original Work.

10.7.4 4) Exclusions From License Grant

Neither the names of Licensor, nor the names of any contributors to the Original Work, nor any of their trademarks or service marks, may be used to endorse or promote products derived from this Original Work without express prior permission of the Licensor. Except as expressly stated herein, nothing in this License grants any license to Licensor’s trademarks, copyrights, patents, trade secrets or any other intellectual property. No patent license is granted to make,

use, sell, offer for sale, have made, or import embodiments of any patent claims other than the licensed claims defined in Section 2) No license is granted to the trademarks of Licensor even if such marks are included in the Original Work. Nothing in this License shall be interpreted to prohibit Licensor from licensing under terms different from this License any Original Work that Licensor otherwise would have a right to license.

10.7.5 5) External Deployment

The term “External Deployment” means the use, distribution, or communication of the Original Work or Derivative Works in any way such that the Original Work or Derivative Works may be used by anyone other than You, whether those works are distributed or communicated to those persons or made available as an application intended for use over a network. As an express condition for the grants of license hereunder, You must treat any External Deployment by You of the Original Work or a Derivative Work as a distribution under section 1(c).

10.7.6 6) Attribution Rights

You must retain, in the Source Code of any Derivative Works that You create, all copyright, patent, or trademark notices from the Source Code of the Original Work, as well as any notices of licensing and any descriptive text identified therein as an “Attribution Notice.” You must cause the Source Code for any Derivative Works that You create to carry a prominent Attribution Notice reasonably calculated to inform recipients that You have modified the Original Work.

10.7.7 7) Warranty of Provenance and Disclaimer of Warranty

Licensor warrants that the copyright in and to the Original Work and the patent rights granted herein by Licensor are owned by the Licensor or are sublicensed to You under the terms of this License with the permission of the contributor(s) of those copyrights and patent rights. Except as expressly stated in the immediately preceding sentence, the Original Work is provided under this License on an “AS IS” BASIS and WITHOUT WARRANTY, either express or implied, including, without limitation, the warranties of non-infringement, merchantability or fitness for a particular purpose. THE ENTIRE RISK AS TO THE QUALITY OF THE ORIGINAL WORK IS WITH YOU. This DISCLAIMER OF WARRANTY constitutes an essential part of this License. No license to the Original Work is granted by this License except under this disclaimer.

10.7.8 8) Limitation of Liability

Under no circumstances and under no legal theory, whether in tort (including negligence), contract, or otherwise, shall the Licensor be liable to anyone for any indirect, special, incidental, or consequential damages of any character arising as a result of this License or the use of the Original Work including, without limitation, damages for loss of goodwill, work stoppage, computer failure or malfunction, or any and all other commercial damages or losses. This limitation of liability shall not apply to the extent applicable law prohibits such limitation.

10.7.9 9) Acceptance and Termination

If, at any time, You expressly assented to this License, that assent indicates your clear and irrevocable acceptance of this License and all of its terms and conditions. If You distribute or communicate copies of the Original Work or a Derivative Work, You must make a reasonable effort under the circumstances to obtain the express assent of recipients to the terms of this License. This License conditions your rights to undertake the activities listed in Section 1, including your right to create Derivative Works based upon the Original Work, and doing so without honoring these terms and conditions is prohibited by copyright law and international treaty. Nothing in this License is intended to affect copyright exceptions and limitations (including “fair use” or “fair dealing”). This License shall terminate

immediately and You may no longer exercise any of the rights granted to You by this License upon your failure to honor the conditions in Section 1(c).

10.7.10 10) Termination for Patent Action

This License shall terminate automatically and You may no longer exercise any of the rights granted to You by this License as of the date You commence an action, including a cross-claim or counterclaim, against Licensor or any licensee alleging that the Original Work infringes a patent. This termination provision shall not apply for an action alleging patent infringement by combinations of the Original Work with other software or hardware.

10.7.11 11) Jurisdiction, Venue and Governing Law

Any action or suit relating to this License may be brought only in the courts of a jurisdiction wherein the Licensor resides or in which Licensor conducts its primary business, and under the laws of that jurisdiction excluding its conflict-of-law provisions. The application of the United Nations Convention on Contracts for the International Sale of Goods is expressly excluded. Any use of the Original Work outside the scope of this License or after its termination shall be subject to the requirements and penalties of copyright or patent law in the appropriate jurisdiction. This section shall survive the termination of this License.

10.7.12 12) Attorneys' Fees

In any action to enforce the terms of this License or seeking damages relating thereto, the prevailing party shall be entitled to recover its costs and expenses, including, without limitation, reasonable attorneys' fees and costs incurred in connection with such action, including any appeal of such action. This section shall survive the termination of this License.

10.7.13 13) Miscellaneous

If any provision of this License is held to be unenforceable, such provision shall be reformed only to the extent necessary to make it enforceable.

10.7.14 14) Definition of "You" in This License

"You" throughout this License, whether in upper or lower case, means an individual or a legal entity exercising rights under, and complying with all of the terms of, this License. For legal entities, "You" includes any entity that controls, is controlled by, or is under common control with you. For purposes of this definition, "control" means (i) the power, direct or indirect, to cause the direction or management of such entity, whether by contract or otherwise, or (ii) ownership of fifty percent (50%) or more of the outstanding shares, or (iii) beneficial ownership of such entity.

10.7.15 15) Right to Use

You may use the Original Work in all ways not otherwise restricted or conditioned by this License or by law, and Licensor promises not to interfere with or be responsible for such uses by You.

10.7.16 16) Modification of This License

This License is Copyright © 2005 Lawrence Rosen. Permission is granted to copy, distribute, or communicate this License without modification. Nothing in this License permits You to modify this License as applied to the Original Work or to Derivative Works. However, You may modify the text of this License and copy, distribute or communicate your modified version (the “Modified License”) and apply it to other original works of authorship subject to the following conditions: (i) You may not indicate in any way that your Modified License is the “Academic Free License” or “AFL” and you may not use those names in the name of your Modified License; (ii) You must replace the notice specified in the first paragraph above with the notice “Licensed under <insert your license name here>” or with a notice of your own that is not confusingly similar to the notice in this License; and (iii) You may not claim that your original works are open source software unless your Modified License has been approved by Open Source Initiative (OSI) and You comply with its license review and certification process.

10.8 CodeIgniter Overview

The following pages describe the broad concepts behind CodeIgniter:

10.8.1 Getting Started With CodeIgniter

Any software application requires some effort to learn. We’ve done our best to minimize the learning curve while making the process as enjoyable as possible.

The first step is to *install* CodeIgniter, then read all the topics in the **Introduction** section of the Table of Contents.

Next, read each of the **General Topics** pages in order. Each topic builds on the previous one, and includes code examples that you are encouraged to try.

Once you understand the basics you’ll be ready to explore the **Class Reference** and **Helper Reference** pages to learn to utilize the native libraries and helper files.

Feel free to take advantage of our [Community Forums](#) if you have questions or problems, and our [Wiki](#) to see code examples posted by other users.

10.8.2 CodeIgniter at a Glance

CodeIgniter is an Application Framework

CodeIgniter is a toolkit for people who build web applications using PHP. Its goal is to enable you to develop projects much faster than you could if you were writing code from scratch, by providing a rich set of libraries for commonly needed tasks, as well as a simple interface and logical structure to access these libraries. CodeIgniter lets you creatively focus on your project by minimizing the amount of code needed for a given task.

CodeIgniter is Free

CodeIgniter is licensed under an Apache/BSD-style open source license so you can use it however you please. For more information please read the *license agreement*.

CodeIgniter is Light Weight

Truly light weight. The core system requires only a few very small libraries. This is in stark contrast to many frameworks that require significantly more resources. Additional libraries are loaded dynamically upon request, based on your needs for a given process, so the base system is very lean and quite fast.

CodeIgniter is Fast

Really fast. We challenge you to find a framework that has better performance than CodeIgniter.

CodeIgniter Uses M-V-C

CodeIgniter uses the Model-View-Controller approach, which allows great separation between logic and presentation. This is particularly good for projects in which designers are working with your template files, as the code these files contain will be minimized. We describe MVC in more detail on its own page.

CodeIgniter Generates Clean URLs

The URLs generated by CodeIgniter are clean and search-engine friendly. Rather than using the standard “query string” approach to URLs that is synonymous with dynamic systems, CodeIgniter uses a segment-based approach:

`example.com/news/article/345`

Note: By default the `index.php` file is included in the URL but it can be removed using a simple `.htaccess` file.

CodeIgniter Packs a Punch

CodeIgniter comes with full-range of libraries that enable the most commonly needed web development tasks, like accessing a database, sending email, validating form data, maintaining sessions, manipulating images, working with XML-RPC data and much more.

CodeIgniter is Extensible

The system can be easily extended through the use of your own libraries, helpers, or through class extensions or system hooks.

CodeIgniter Does Not Require a Template Engine

Although CodeIgniter *does* come with a simple template parser that can be optionally used, it does not force you to use one. Template engines simply can not match the performance of native PHP, and the syntax that must be learned to use a template engine is usually only marginally easier than learning the basics of PHP. Consider this block of PHP code:

```
<ul>
<?php foreach ($addressbook as $name):?>
    <li><?=$name?></li>
<?php endforeach; ?>
</ul>
```

Contrast this with the pseudo-code used by a template engine:

```
<ul>
{foreach from=$addressbook item="name"}
    <li>{$name}</li>
{/foreach}
</ul>
```

Yes, the template engine example is a bit cleaner, but it comes at the price of performance, as the pseudo-code must be converted back into PHP to run. Since one of our goals is *maximum performance*, we opted to not require the use of a template engine.

CodeIgniter is Thoroughly Documented

Programmers love to code and hate to write documentation. We're no different, of course, but since documentation is **as important** as the code itself, we are committed to doing it. Our source code is extremely clean and well commented as well.

CodeIgniter has a Friendly Community of Users

Our growing community of users can be seen actively participating in our [Community Forums](#).

10.8.3 CodeIgniter Features

Features in and of themselves are a very poor way to judge an application since they tell you nothing about the user experience, or how intuitively or intelligently it is designed. Features don't reveal anything about the quality of the code, or the performance, or the attention to detail, or security practices. The only way to really judge an app is to try it and get to know the code. Installing CodeIgniter is child's play so we encourage you to do just that. In the mean time here's a list of CodeIgniter's main features.

- Model-View-Controller Based System
- Extremely Light Weight
- Full Featured database classes with support for several platforms.
- Query Builder Database Support
- Form and Data Validation
- Security and XSS Filtering
- Session Management
- Email Sending Class. Supports Attachments, HTML/Text email, multiple protocols (sendmail, SMTP, and Mail) and more.
- Image Manipulation Library (cropping, resizing, rotating, etc.). Supports GD, ImageMagick, and NetPBM
- File Uploading Class
- FTP Class
- Localization
- Pagination
- Data Encryption
- Benchmarking
- Full Page Caching

- Error Logging
- Application Profiling
- Calendaring Class
- User Agent Class
- Zip Encoding Class
- Template Engine Class
- Trackback Class
- XML-RPC Library
- Unit Testing Class
- Search-engine Friendly URLs
- Flexible URI Routing
- Support for Hooks and Class Extensions
- Large library of “helper” functions

10.8.4 Application Flow Chart

The following graphic illustrates how data flows throughout the system:

1. The index.php serves as the front controller, initializing the base resources needed to run CodeIgniter.
2. The Router examines the HTTP request to determine what should be done with it.
3. If a cache file exists, it is sent directly to the browser, bypassing the normal system execution.
4. Security. Before the application controller is loaded, the HTTP request and any user submitted data is filtered for security.
5. The Controller loads the model, core libraries, helpers, and any other resources needed to process the specific request.
6. The finalized View is rendered then sent to the web browser to be seen. If caching is enabled, the view is cached first so that on subsequent requests it can be served.

10.8.5 Model-View-Controller

CodeIgniter is based on the Model-View-Controller development pattern. MVC is a software approach that separates application logic from presentation. In practice, it permits your web pages to contain minimal scripting since the presentation is separate from the PHP scripting.

- The **Model** represents your data structures. Typically your model classes will contain functions that help you retrieve, insert, and update information in your database.
- The **View** is the information that is being presented to a user. A View will normally be a web page, but in CodeIgniter, a view can also be a page fragment like a header or footer. It can also be an RSS page, or any other type of “page”.
- The **Controller** serves as an *intermediary* between the Model, the View, and any other resources needed to process the HTTP request and generate a web page.

CodeIgniter has a fairly loose approach to MVC since Models are not required. If you don't need the added separation, or find that maintaining models requires more complexity than you want, you can ignore them and build your application minimally using Controllers and Views. CodeIgniter also enables you to incorporate your own existing scripts, or even develop core libraries for the system, enabling you to work in a way that makes the most sense to you.

10.8.6 Design and Architectural Goals

Our goal for CodeIgniter is maximum performance, capability, and flexibility in the smallest, lightest possible package.

To meet this goal we are committed to benchmarking, re-factoring, and simplifying at every step of the development process, rejecting anything that doesn't further the stated objective.

From a technical and architectural standpoint, CodeIgniter was created with the following objectives:

- **Dynamic Instantiation.** In CodeIgniter, components are loaded and routines executed only when requested, rather than globally. No assumptions are made by the system regarding what may be needed beyond the minimal core resources, so the system is very light-weight by default. The events, as triggered by the HTTP request, and the controllers and views you design will determine what is invoked.
- **Loose Coupling.** Coupling is the degree to which components of a system rely on each other. The less components depend on each other the more reusable and flexible the system becomes. Our goal was a very loosely coupled system.
- **Component Singularity.** Singularity is the degree to which components have a narrowly focused purpose. In CodeIgniter, each class and its functions are highly autonomous in order to allow maximum usefulness.

CodeIgniter is a dynamically instantiated, loosely coupled system with high component singularity. It strives for simplicity, flexibility, and high performance in a small footprint package.

10.9 Server Requirements

- [PHP](#) version 5.2.4 or newer.
- A Database is required for most web application programming. Currently supported databases are: - MySQL (5.1+) via the *mysql* (deprecated), *mysqli* and *pdo* drivers - Oracle via the *oci8* and *pdo* drivers - PostgreSQL via the *postgre* and *pdo* drivers - MS SQL via the *mssql*, *sqlsrv* (version 2005 and above only) and *pdo* drivers - SQLite via the *sqlite* (version 2), *sqlite3* (version 3) and *pdo* drivers - CUBRID via the *cubrid* and *pdo* drivers - Interbase/Firebird via the *ibase* and *pdo* drivers - ODBC via the *odbc* and *pdo* drivers (you should know that ODBC is actually an abstraction layer)

10.10 Welcome to CodeIgniter

CodeIgniter is an Application Development Framework - a toolkit - for people who build web sites using PHP. Its goal is to enable you to develop projects much faster than you could if you were writing code from scratch, by providing a rich set of libraries for commonly needed tasks, as well as a simple interface and logical structure to access these libraries. CodeIgniter lets you creatively focus on your project by minimizing the amount of code needed for a given task.

10.10.1 Who is CodeIgniter For?

CodeIgniter is right for you if:

- You want a framework with a small footprint.

- You need exceptional performance.
- You need broad compatibility with standard hosting accounts that run a variety of PHP versions and configurations.
- You want a framework that requires nearly zero configuration.
- You want a framework that does not require you to use the command line.
- You want a framework that does not require you to adhere to restrictive coding rules.
- You are not interested in large-scale monolithic libraries like PEAR.
- You do not want to be forced to learn a templating language (although a template parser is optionally available if you desire one).
- You eschew complexity, favoring simple solutions.
- You need clear, thorough documentation.

10.11 Installation Instructions

CodeIgniter is installed in four steps:

1. Unzip the package.
2. Upload the CodeIgniter folders and files to your server. Normally the `index.php` file will be at your root.
3. Open the `application/config/config.php` file with a text editor and set your base URL. If you intend to use encryption or sessions, set your encryption key.
4. If you intend to use a database, open the `application/config/database.php` file with a text editor and set your database settings.

If you wish to increase security by hiding the location of your CodeIgniter files you can rename the system and application folders to something more private. If you do rename them, you must open your main `index.php` file and set the `$system_path` and `$application_folder` variables at the top of the file with the new name you've chosen.

For the best security, both the system and any application folders should be placed above web root so that they are not directly accessible via a browser. By default, `.htaccess` files are included in each folder to help prevent direct access, but it is best to remove them from public access entirely in case the web server configuration changes or doesn't abide by the `.htaccess`.

If you would like to keep your views public it is also possible to move the views folder out of your application folder.

After moving them, open your main `index.php` file and set the `$system_path`, `$application_folder` and `$view_folder` variables, preferably with a full path, e.g. `'/www/MyUser/system'`.

One additional measure to take in production environments is to disable PHP error reporting and any other development-only functionality. In CodeIgniter, this can be done by setting the `ENVIRONMENT` constant, which is more fully described on the *security page*.

That's it!

If you're new to CodeIgniter, please read the *Getting Started* section of the User Guide to begin learning how to build dynamic PHP applications. Enjoy!

10.11.1 Downloading CodeIgniter

- [CodeIgniter v3.0.0 \(Current version\)](#)

- CodeIgniter v2.1.4 (MD5 Checksum: e74a296c1d412a855c025b9cd468a513)
- CodeIgniter v2.1.3 (MD5 Checksum: 781d06be06eaa36f10759ef82c8594d5)
- CodeIgniter v2.1.2 (MD5 Checksum: c7a2980dff2774c97bd38bfbf450d8d5)
- CodeIgniter v2.1.1 (MD5 Checksum: c4aa5f188f4ff16f919607b46a16c76c)
- CodeIgniter v2.1.0 (MD5 Checksum: 8cb676b0f831114935d7dd1ae2e0d490)
- CodeIgniter v2.0.3 (MD5 Checksum: 910475d50daf088bdd949c3d35b444d9)
- CodeIgniter v2.0.2 (MD5 Checksum: e75bab8cf27d2fb2483c5bb61b85a524)
- CodeIgniter v2.0.1 (MD5 Checksum: 675aa95896bfb16467436c0484f15f1f)
- CodeIgniter v2.0.0 (MD5 Checksum: bd657863de45dbb397f3b3dbc4f13abb)
- CodeIgniter v1.7.3 (MD5 Checksum: 16f50e7df4f44c1defe18355131049e9)
- CodeIgniter v1.7.2 (MD5 Checksum: ff2f4d1b3ab921f91e006f38b3ae6540)
- CodeIgniter v1.7.1 (MD5 Checksum: deca9709cf21b26dc0e4ec040b37e866)
- CodeIgniter v1.7.0 (MD5 Checksum: 28037f2071f940d8756864460d949045)
- CodeIgniter v1.6.3 (MD5 Checksum: 5ffab52b39b235ed6bd08ee5dd64d2f6)

- CodeIgniter v1.1 (MD5 Checksum: bf4cabb6a3ea3122a974270b8044befb)
- CodeIgniter v1.0 (MD5 Checksum: 427ca4255e2bdaacee976de1aa143ea0)

GitHub

Git is a distributed version control system.

Public Git access is available at [GitHub](https://github.com). Please note that while every effort is made to keep this code base functional, we cannot guarantee the functionality of code taken from the develop branch.

Beginning with version 2.0.3, stable versions are also available via [GitHub Releases](#).

10.11.2 Troubleshooting

If you find that no matter what you put in your URL only your default page is loading, it might be that your server does not support the `PATH_INFO` variable needed to serve search-engine friendly URLs. As a first step, open your `application/config/config.php` file and look for the URI Protocol information. It will recommend that you try a couple alternate settings. If it still doesn't work after you've tried this you'll need to force CodeIgniter to add a question mark to your URLs. To do this open your `application/config/config.php` file and change this:

```
$config['index_page'] = "index.php";
```

To this:

```
$config['index_page'] = "index.php?";
```

10.11.3 Upgrading From Beta 1.0 to Final 1.2

To upgrade to Version 1.2 please replace the following directories with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- drivers
- helpers
- init
- language
- libraries
- plugins
- scaffolding

Please also replace your local copy of the user guide with the new version.

10.11.4 Upgrading from 1.2 to 1.3

: The instructions on this page assume you are running version 1.2. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the `index.php` file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- `application/models/` (new for 1.3)
- `codeigniter` (new for 1.3)

- drivers
- helpers
- init
- language
- libraries
- plugins
- scaffolding

Step 2: Update your error files

Version 1.3 contains two new error templates located in application/errors, and for naming consistency the other error templates have been renamed.

If you **have not** customized any of the error templates simply replace this folder:

- application/errors/

If you **have** customized your error templates, rename them as follows:

- 404.php = error_404.php
- error.php = error_general.php
- error_db.php (new)
- error_php.php (new)

Step 3: Update your index.php file

Please open your main index.php file (located at your root). At the very bottom of the file, change this:

```
require_once BASEPATH.'libraries/Front_controller'.EXT;
```

To this:

```
require_once BASEPATH.'codeigniter/CodeIgniter'.EXT;
```

Step 4: Update your config.php file

Open your application/config/config.php file and add these new items:

```
/*
|-----
| URL suffix
|-----
|
| This option allows you to add a suffix to all URLs.
| For example, if a URL is this:
|
| example.com/index.php/products/view/shoes
|
| You can optionally add a suffix, like ".html",
| making the page appear to be of a certain type:
|
```

```

| example.com/index.php/products/view/shoes.html
|
*/
$config['url_suffix'] = "";

/*
|-----
| Enable Query Strings
|-----
|
| By default CodeIgniter uses search-engine and
| human-friendly segment based URLs:
|
| example.com/who/what/where/
|
| You can optionally enable standard query string
| based URLs:
|
| example.com?who=me&what=something&where=here
|
| Options are: TRUE or FALSE (boolean)
|
| The two other items let you set the query string "words"
| that will invoke your controllers and functions:
| example.com/index.php?c=controller&m=function
|
*/
$config['enable_query_strings'] = FALSE;
$config['controller_trigger'] = 'c';
$config['function_trigger'] = 'm';

```

Step 5: Update your database.php file

Open your application/config/database.php file and add these new items:

```

$db['default']['dbprefix'] = "";
$db['default']['active_r'] = TRUE;

```

Step 6: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.5 Upgrading from 1.3 to 1.3.1

: The instructions on this page assume you are running version 1.3. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- drivers
- init/init_unit_test.php (new for 1.3.1)
- language/
- libraries
- scaffolding

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.6 Upgrading from 1.3.1 to 1.3.2

: The instructions on this page assume you are running version 1.3.1. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- drivers
- init
- libraries

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.7 Upgrading from 1.3.2 to 1.3.3

: The instructions on this page assume you are running version 1.3.2. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- codeigniter
- drivers
- helpers
- init
- libraries

Step 2: Update your Models

If you are **NOT** using CodeIgniter’s *Models* feature disregard this step.

As of version 1.3.3, CodeIgniter does **not** connect automatically to your database when a model is loaded. This allows you greater flexibility in determining which databases you would like used with your models. If your application is not connecting to your database prior to a model being loaded you will have to update your code. There are several options for connecting, *as described here*.

Step 3: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.8 Upgrading from 1.3.3 to 1.4.0

: The instructions on this page assume you are running version 1.3.3. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- application/config/**hooks.php**
- application/config/**mimes.php**
- codeigniter
- drivers
- helpers
- init
- language

- libraries
- scaffolding

Step 2: Update your config.php file

Open your application/config/config.php file and add these new items:

```
/*
|-----
| Enable/Disable System Hooks
|-----
|
| If you would like to use the "hooks" feature you must enable it by
| setting this variable to TRUE (boolean).  See the user guide for details.
|
*/
$config['enable_hooks'] = FALSE;

/*
|-----
| Allowed URL Characters
|-----
|
| This lets you specify which characters are permitted within your URLs.
| When someone tries to submit a URL with disallowed characters they will
| get a warning message.
|
| As a security measure you are STRONGLY encouraged to restrict URLs to
| as few characters as possible.  By default only these are allowed: a-z 0-9~%.:_-
|
| Leave blank to allow all characters -- but only if you are insane.
|
| DO NOT CHANGE THIS UNLESS YOU FULLY UNDERSTAND THE REPERCUSSIONS!!
|
*/
$config['permitted_uri_chars'] = 'a-z 0-9~%.:_-';
```

Step 3: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.9 Upgrading from 1.4.0 to 1.4.1

: The instructions on this page assume you are running version 1.4.0. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace the following directories in your “system” folder with the new versions:

: If you have any custom developed files in these folders please make copies of them first.

- codeigniter
- drivers
- helpers
- libraries

Step 2: Update your config.php file

Open your application/config/config.php file and add this new item:

```
/*
|-----
| Output Compression
|-----
|
| Enables Gzip output compression for faster page loads.  When enabled,
| the output class will test whether your server supports Gzip.
| Even if it does, however, not all browsers support compression
| so enable only if you are reasonably sure your visitors can handle it.
|
| VERY IMPORTANT:  If you are getting a blank page when compression is enabled it
| means you are prematurely outputting something to your browser. It could
| even be a line of whitespace at the end of one of your scripts.  For
| compression to work, nothing can be sent before the output buffer is called
| by the output class.  Do not "echo" any values with compression enabled.
|
*/
$config['compress_output'] = FALSE;
```

Step 3: Rename an Autoload Item

Open the following file: application/config/autoload.php

Find this array item:

```
$autoload['core'] = array();
```

And rename it to this:

```
$autoload['libraries'] = array();
```

This change was made to improve clarity since some users were not sure that their own libraries could be auto-loaded.

Step 4: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.10 Upgrading from 1.4.1 to 1.5.0

: The instructions on this page assume you are running version 1.4.1. If you have not upgraded to that version please

do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- application/config/user_agents.php (new file for 1.5)
- application/config/smileys.php (new file for 1.5)
- codeigniter/
- database/ (new folder for 1.5. Replaces the “drivers” folder)
- helpers/
- language/
- libraries/
- scaffolding/

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your database.php file

Open your application/config/database.php file and add these new items:

```
$db['default']['cache_on'] = FALSE;
$db['default']['cachedir'] = '';
```

Step 3: Update your config.php file

Open your application/config/config.php file and ADD these new items:

```
/*
|-----
| Class Extension Prefix
|-----
|
| This item allows you to set the filename/classname prefix when extending
| native libraries. For more information please see the user guide:
|
| http://codeigniter.com/user_guide/general/core_classes.html
| http://codeigniter.com/user_guide/general/creating_libraries.html
|
*/
$config['subclass_prefix'] = 'MY_';

/*
|-----
| Rewrite PHP Short Tags
|-----
|
| If your PHP installation does not have short tag support enabled CI
```

```
| can rewrite the tags on-the-fly, enabling you to utilize that syntax
| in your view files. Options are TRUE or FALSE (boolean)
|
*/
$config['rewrite_short_tags'] = FALSE;
```

In that same file REMOVE this item:

```
/*
|-----
| Enable/Disable Error Logging
|-----
|
| If you would like errors or debug messages logged set this variable to
| TRUE (boolean). Note: You must set the file permissions on the "logs" folder
| such that it is writable.
|
*/
$config['log_errors'] = FALSE;
```

Error logging is now disabled simply by setting the threshold to zero.

Step 4: Update your main index.php file

If you are running a stock index.php file simply replace your version with the new one.

If your index.php file has internal modifications, please add your modifications to the new file and use it.

Step 5: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.11 Upgrading from 1.5.0 to 1.5.2

: The instructions on this page assume you are running version 1.5.0 or 1.5.1. If you have not upgraded to that version please do so first.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/helpers/download_helper.php
- system/helpers/form_helper.php
- system/libraries/Table.php
- system/libraries/User_agent.php
- system/libraries/Exceptions.php
- system/libraries/Input.php
- system/libraries/Router.php

- system/libraries/Loader.php
- system/libraries/Image_lib.php
- system/language/english/unit_test_lang.php
- system/database/DB_active_rec.php
- system/database/drivers/mysqli/mysqli_driver.php
- codeigniter/

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.12 Upgrading from 1.5.2 to 1.5.3

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/database/drivers
- system/helpers
- system/libraries/Input.php
- system/libraries/Loader.php
- system/libraries/Profiler.php
- system/libraries/Table.php

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.13 Upgrading from 1.5.3 to 1.5.4

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- application/config/mimes.php
- system/codeigniter

- system/database
- system/helpers
- system/libraries
- system/plugins

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Add charset to your config.php

Add the following to application/config/config.php

```
/*
|-----
| Default Character Set
|-----
|
| This determines which character set is used by default in various methods
| that require a character set to be provided.
|
*/
$config['charset'] = "UTF-8";
```

Step 3: Autoloading language files

If you want to autoload any language files, add this line to application/config/autoload.php

```
$autoload['language'] = array();
```

Step 4: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.14 Upgrading from 1.5.4 to 1.6.0

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/libraries
- system/plugins
- system/language

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Add time_to_update to your config.php

Add the following to application/config/config.php with the other session configuration options

```
$config['sess_time_to_update'] = 300;
```

Step 3: Add \$autoload['model']

Add the following to application/config/autoload.php

```
/*
| -----
| Auto-load Model files
| -----
| Prototype:
|
| $autoload['model'] = array('my_model');
|
*/

$autoload['model'] = array();
```

Step 4: Add to your database.php

Make the following changes to your application/config/database.php file:

Add the following variable above the database configuration options, with \$active_group

```
$active_record = TRUE;
```

Remove the following from your database configuration options

```
$db['default']['active_r'] = TRUE;
```

Add the following to your database configuration options

```
$db['default']['char_set'] = "utf8";
$db['default']['dbcollat'] = "utf8_general_ci";
```

Step 5: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.15 Upgrading from 1.6.0 to 1.6.1

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.16 Upgrading from 1.6.1 to 1.6.2

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Encryption Key

If you are using sessions, open up application/config/config.php and verify you’ve set an encryption key.

Step 3: Constants File

Copy /application/config/constants.php to your installation, and modify if necessary.

Step 4: Mimes File

Replace /application/config/mimes.php with the downloaded version. If you’ve added custom mime types, you’ll need to re-add them.

Step 5: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.17 Upgrading from 1.6.2 to 1.6.3

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.18 Upgrading from 1.6.3 to 1.7.0

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your Session Table

If you are using the Session class in your application, AND if you are storing session data to a database, you must add a new column named `user_data` to your session table. Here is an example of what this column might look like for MySQL:

```
user_data text NOT NULL
```

To add this column you will run a query similar to this:

```
ALTER TABLE `ci_sessions` ADD `user_data` text NOT NULL
```

You'll find more information regarding the new Session functionality in the *Session class* page.

Step 3: Update your Validation Syntax

This is an **optional**, but recommended step, for people currently using the Validation class. CI 1.7 introduces a new *Form Validation class*, which deprecates the old Validation library. We have left the old one in place so that existing applications that use it will not break, but you are encouraged to migrate to the new version as soon as possible. Please read the user guide carefully as the new library works a little differently, and has several new features.

Step 4: Update your user guide

Please replace your local copy of the user guide with the new version, including the image files.

10.11.19 Upgrading from 1.7.0 to 1.7.1

Before performing an update you should take your site offline by replacing the `index.php` file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please replace your local copy of the user guide with the new version, including the image files.

10.11.20 Upgrading from 1.7.1 to 1.7.2

Before performing an update you should take your site offline by replacing the `index.php` file with a static one.

Step 1: Update your CodeIgniter files

Replace these files and directories in your “system” folder with the new versions:

- system/codeigniter
- system/database
- system/helpers
- system/language
- system/libraries
- index.php

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Remove header() from 404 error template

If you are using header() in your 404 error template, such as the case with the default error_404.php template shown below, remove that line of code.

```
<?php header("HTTP/1.1 404 Not Found"); ?>
```

404 status headers are now properly handled in the show_404() method itself.

Step 3: Confirm your system_path

In your updated index.php file, confirm that the \$system_path variable is set to your application’s system folder.

Step 4: Update your user guide

Please replace your local copy of the user guide with the new version, including the image files.

10.11.21 Upgrading from 1.7.2 to 2.0.0

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Update Instructions

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder **except** your application folder.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Adjust `get_dir_file_info()` where necessary

Version 2.0.0 brings a non-backwards compatible change to `get_dir_file_info()` in the *File Helper*. Non-backwards compatible changes are extremely rare in CodeIgniter, but this one we feel was warranted due to how easy it was to create serious server performance issues. If you *need* recursiveness where you are using this helper function, change such instances, setting the second parameter, `$top_level_only` to `FALSE`:

```
get_dir_file_info('/path/to/directory', FALSE);
```

Step 3: Convert your Plugins to Helpers

2.0.0 gets rid of the “Plugin” system as their functionality was identical to Helpers, but non-extensible. You will need to rename your plugin files from `filename_pi.php` to `filename_helper.php`, move them to your helpers folder, and change all instances of:

```
$this->load->plugin('foo');
```

to

```
$this->load->helper('foo');
```

Step 4: Update stored encrypted data

: If your application does not use the Encryption library, does not store Encrypted data permanently, or is on an environment that does not support Mcrypt, you may skip this step.

The Encryption library has had a number of improvements, some for encryption strength and some for performance, that has an unavoidable consequence of making it no longer possible to decode encrypted data produced by the original version of this library. To help with the transition, a new method has been added, `encode_from_legacy()` that will decode the data with the original algorithm and return a re-encoded string using the improved methods. This will enable you to easily replace stale encrypted data with fresh in your applications, either on the fly or en masse.

Please read how to use this method in the Encryption library documentation.

Step 5: Remove loading calls for the compatibility helper.

The compatibility helper has been removed from the CodeIgniter core. All methods in it should be natively available in supported PHP versions.

Step 6: Update Class extension

All core classes are now prefixed with `CI_`. Update Models and Controllers to extend `CI_Model` and `CI_Controller`, respectively.

Step 7: Update Parent Constructor calls

All native CodeIgniter classes now use the PHP 5 `__construct()` convention. Please update extended libraries to call `parent::__construct()`.

Step 8: Move any core extensions to application/core

Any extensions to core classes (e.g. MY_Controller.php) in your application/libraries folder must be moved to the new application/core folder.

Step 9: Update your user guide

Please replace your local copy of the user guide with the new version, including the image files.

Update Notes

Please refer to the *2.0.0 Change Log* for full details, but here are some of the larger changes that are more likely to impact your code:

- CodeIgniter now requires PHP 5.2.4.
- Scaffolding has been removed.
- The CAPTCHA plugin is now a *helper*.
- The JavaScript calendar plugin was removed.
- The *system/cache* and *system/logs* directories are now in the application directory.
- The Validation class has been removed. Please see the *Form Validation library*
- “default” is now a reserved name.
- The `xss_clean()` function has moved to the *Security Class*.
- `do_xss_clean()` now returns FALSE if the uploaded file fails XSS checks.
- The *Session Class* requires now the use of an encryption key set in the config file.
- The following deprecated Active Record functions have been removed: `orwhere`, `orlike`, `groupby`, `orhaving`, `orderby`, `getwhere`.
- `_drop_database()` and `_create_database()` functions have been removed from the db utility drivers.
- The `dohash()` function of the *Security helper* has been renamed to `do_hash()` for naming consistency.

The config folder

The following files have been changed:

- `config.php`
- `database.php`
- `mimes.php`
- `routes.php`
- `user_agents.php`

The following files have been added:

- `foreign_chars.php`
- `profiler.php`

10.11.22 Upgrading from 2.0.0 to 2.0.1

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder and replace your index.php file. If any modifications were made to your index.php they will need to be made fresh in this new one.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Replace config/mimes.php

This config file has been updated to contain more mime types, please copy it to application/config/mimes.php.

Step 3: Check for forms posting to default controller

The default behavior for form_open() when called with no parameters used to be to post to the default controller, but it will now just leave an empty action="" meaning the form will submit to the current URL. If submitting to the default controller was the expected behavior it will need to be changed from:

```
echo form_open(); //<form action="" method="post" accept-charset="utf-8">
```

to use either a / or base_url():

```
echo form_open('/'); //<form action="http://example.com/index.php/" method="post" accept-charset="utf-8">
echo form_open(base_url()); //<form action="http://example.com/" method="post" accept-charset="utf-8">
```

10.11.23 Upgrading from 2.0.1 to 2.0.2

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder and replace your index.php file. If any modifications were made to your index.php they will need to be made fresh in this new one.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Remove loading calls for the Security Library

Security has been moved to the core and is now always loaded automatically. Make sure you remove any loading calls as they will result in PHP errors.

Step 3: Move MY_Security

If you are overriding or extending the Security library, you will need to move it to application/core.

csrf_token_name and csrf_hash have changed to protected class properties. Please use security->get_csrf_hash() and security->get_csrf_token_name() to access those values.

10.11.24 Upgrading from 2.0.2 to 2.0.3

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder and replace your index.php file. If any modifications were made to your index.php they will need to be made fresh in this new one.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your main index.php file

If you are running a stock index.php file simply replace your version with the new one.

If your index.php file has internal modifications, please add your modifications to the new file and use it.

Step 3: Replace config/user_agents.php

This config file has been updated to contain more user agent types, please copy it to application/config/user_agents.php.

Step 4: Change references of the EXT constant to “.php”

: The EXT Constant has been marked as deprecated, but has not been removed from the application. You are encouraged to make the changes sooner rather than later.

Step 5: Remove APPPATH.'third_party' from autoload.php

Open application/config/autoload.php, and look for the following:

```
$autoload['packages'] = array(APPPATH.'third_party');
```

If you have not chosen to load any additional packages, that line can be changed to:

```
$autoload['packages'] = array();
```

Which should provide for nominal performance gains if not autoloading packages.

Update Sessions Database Tables

If you are using database sessions with the CI Session Library, please update your ci_sessions database table as follows:

```
CREATE INDEX last_activity_idx ON ci_sessions(last_activity);  
ALTER TABLE ci_sessions MODIFY user_agent VARCHAR(120);
```

10.11.25 Upgrading from 2.0.3 to 2.1.0

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Replace config/user_agents.php

This config file has been updated to contain more user agent types, please copy it to _application/config/user_agents.php*.

Step 3: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.26 Upgrading from 2.1.0 to 2.1.1

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Replace config/mimes.php

This config file has been updated to contain more user mime-types, please copy it to _application/config/mimes.php*.

Step 3: Update your IP address tables

This upgrade adds support for IPv6 IP addresses. In order to store them, you need to enlarge your ip_address columns to 45 characters. For example, CodeIgniter’s session table will need to change

```
ALTER TABLE ci_sessions CHANGE ip_address ip_address varchar(45) default '0' NOT NULL
```

10.11.27 Upgrading from 2.1.1 to 2.1.2

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.28 Upgrading from 2.1.2 to 2.1.3

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your user guide

Please also replace your local copy of the user guide with the new version.

10.11.29 Upgrading from 2.1.3 to 2.1.4

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder.

: If you have any custom developed files in these folders please make copies of them first.

10.11.30 Upgrading from 2.1.4 to 3.0.0

: These upgrade notes are for a version that is yet to be released.

Before performing an update you should take your site offline by replacing the index.php file with a static one.

Step 1: Update your CodeIgniter files

Replace all files and directories in your “system” folder and replace your index.php file. If any modifications were made to your index.php they will need to be made fresh in this new one.

: If you have any custom developed files in these folders please make copies of them first.

Step 2: Update your classes file names

Starting with CodeIgniter 3.0, all class filenames (libraries, drivers, controllers and models) must be named in a Ucfirst-like manner or in other words - they must start with a capital letter.

For example, if you have the following library file:

```
application/libraries/mylibrary.php
```

... then you'll have to rename it to:

```
application/libraries/Mylibrary.php
```

The same goes for driver libraries and extensions and/or overrides of CodeIgniter's own libraries and core classes.

```
application/libraries/MY_email.php application/core/MY_log.php
```

The above files should respectively be renamed to the following:

```
application/libraries/MY_Email.php application/core/MY_Log.php
```

Controllers:

```
application/controllers/welcome.php -> application/controllers/Welcome.php
```

Models:

```
application/models/misc_model.php -> application/models/Misc_model.php
```

Please note that this DOES NOT affect directories, configuration files, views, helpers, hooks and anything else - it is only applied to classes.

You must now follow just one simple rule - class names in Ucfirst and everything else in lowercase.

Step 3: Replace config/mimes.php

This config file has been updated to contain more user mime-types, please copy it to `_application/config/mimes.php*`.

Step 4: Remove \$autoload['core'] from your config/autoload.php

Use of the `$autoload['core']` config array has been deprecated as of CodeIgniter 1.4.1 and is now removed. Move any entries that you might have listed there to `$autoload['libraries']` instead.

Step 5: Move your Log class overrides or extensions

The Log Class is considered as a “core” class and is now located in the **system/core/** directory. Therefore, in order for your Log class overrides or extensions to work, you need to move them to **application/core/**:

```
application/libraries/Log.php -> application/core/Log.php
application/libraries/MY_Log.php -> application/core/MY_Log.php
```

Step 6: Convert your Session usage from library to driver

When you load (or autoload) the Session library, you must now load it as a driver instead of a library. This means calling `$this->load->driver('session')` instead of `$this->load->library('session')` and/or listing 'session' in `$autoload['drivers']` instead of `$autoload['libraries']`.

With the change from a single Session Library to the new Session Driver, two new config items have been added:

- `$config['sess_driver']` selects which driver to initially load. Options are:
 - 'cookie' (the default) for classic CodeIgniter cookie-based sessions
 - 'native' for native PHP Session support
 - the name of a custom driver you have provided (see *Session Driver* for more info)
- `$config['sess_valid_drivers']` provides an array of additional custom drivers to make available for loading

As the new Session Driver library loads the classic Cookie driver by default and always makes 'cookie' and 'native' available as valid drivers, neither of these configuration items are required. However, it is recommended that you add them for clarity and ease of configuration in the future.

If you have written a Session extension, you must move it into a 'Session' sub-directory of 'libraries', following the standard for Drivers. Also beware that some functions which are not part of the external Session API have moved into the drivers, so your extension may have to be broken down into separate library and driver class extensions.

Step 7: Update your config/database.php

Due to 3.0.0's renaming of Active Record to Query Builder, inside your *config/database.php*, you will need to rename the `$active_record` variable to `$query_builder`

```
$active_group = 'default';  
// $active_record = TRUE;  
$query_builder = TRUE;
```

Step 8: Replace your error templates

In CodeIgniter 3.0, the error templates are now considered as views and have been moved to the `_application/views/errors*` directory.

Furthermore, we've added support for CLI error templates in plain-text format that unlike HTML, is suitable for the command line. This of course requires another level of separation.

It is safe to move your old templates from `_application/errors*` to `_application/views/errors/html*`, but you'll have to copy the new `_application/views/errors/cli*` directory from the CodeIgniter archive.

Step 9: Update your config/routes.php containing (:any)

Historically, CodeIgniter has always provided the `:any` wildcard in routing, with the intention of providing a way to match any character **within** an URI segment.

However, the `:any` wildcard is actually just an alias for a regular expression and used to be executed in that manner as `.+`. This is considered a bug, as it also matches the `/` (forward slash) character, which is the URI segment delimiter and that was never the intention. In CodeIgniter 3, the `:any` wildcard will now represent `[^/]+`, so that it will not match a forward slash.

There are certainly many developers that have utilized this bug as an actual feature. If you're one of them and want to match a forward slash, please use the `.+` regular expression:

```
(.+)    // matches ANYTHING
(:any)  // matches any character, except for '/'
```

Step 10: Many functions now return NULL instead of FALSE on missing items

Many methods and functions now return NULL instead of FALSE when the required items don't exist:

- *Config Class*
 - `config->item()`
 - `config->slash_item()`
- *Input Class*
 - `input->get()`
 - `input->post()`
 - `input->get_post()`
 - `input->cookie()`
 - `input->server()`
 - `input->input_stream()`
 - `input->get_request_header()`
- *Session Class*
 - `session->userdata()`
 - `session->flashdata()`
- *URI Class*
 - `uri->segment()`
 - `uri->rsegment()`
- *Array Helper*
 - `element()`
 - `elements()`

Step 11: Update usage of Input Class's get_post() method

Previously, the *Input Class* method `get_post()` was searching first in POST data, then in GET data. This method has been modified so that it searches in GET then in POST, as its name suggests.

A method has been added, `post_get()`, which searches in POST then in GET, as `get_post()` was doing before.

Step 12: Update usage of Directory Helper's directory_map() function

In the resulting array, directories now end with a trailing directory separator (i.e. a slash, usually).

Step 13: Update usage of Database Forge's `drop_table()` method

Up until now, `drop_table()` added an IF EXISTS clause by default or it didn't work at all with some drivers. In CodeIgniter 3.0, the IF EXISTS condition is no longer added by default and has an optional second parameter that allows that instead and is set to FALSE by default.

If your application relies on IF EXISTS, you'll have to change its usage.

```
// Now produces just DROP TABLE `table_name`
$this->dbforge->drop_table('table_name');

// Produces DROP TABLE IF EXISTS `table_name`
$this->dbforge->drop_table('table_name', TRUE);
```

: The given example uses MySQL-specific syntax, but it should work across all drivers with the exception of ODBC.

Step 14: Change usage of Email library with multiple emails

The *Email Library* will automatically clear the set parameters after successfully sending emails. To override this behaviour, pass FALSE as the first parameter in the `send()` method:

```
if ($this->email->send(FALSE))
{
    // Parameters won't be cleared
}
```

Step 15: Update your Form_validation language lines

Two improvements have been made to the *Form Validation Library's* *language* files and error messages format:

- *Language Library* line keys now must be prefixed with **form_validation_** in order to avoid collisions:

```
// Old
$lang['rule'] = ...

// New
$lang['form_validation_rule'] = ...
```

- The error messages format has been changed to use named parameters, to allow more flexibility than what *sprintf()* offers:

```
// Old
'The %s field does not match the %s field.'

// New
'The {field} field does not match the {param} field.'
```

: The old formatting still works, but the non-prefixed line keys are DEPRECATED and scheduled for removal in CodeIgniter 3.1+. Therefore you're encouraged to update its usage sooner rather than later.

Step 16: Remove usage of (previously) deprecated functionalities

In addition to the `$autoload['core']` configuration setting, there's a number of other functionalities that have been removed in CodeIgniter 3.0.0:

The SHA1 library

The previously deprecated SHA1 library has been removed, alter your code to use PHP's native `sha1()` function to generate a SHA1 hash.

Additionally, the `sha1()` method in the *Encryption Library* has been removed.

The EXT constant

Usage of the `EXT` constant has been deprecated since dropping support for PHP 4. There's no longer a need to maintain different filename extensions and in this new CodeIgniter version, the `EXT` constant has been removed. Use just `'php'` instead.

Smiley helper `js_insert_smiley()`

Smiley Helper function `js_insert_smiley()` has been deprecated since CodeIgniter 1.7.2 and is now removed. You'll need to switch to `smiley_js()` instead.

Security helper `do_hash()`

Security Helper function `do_hash()` is now just an alias for PHP's native `hash()` function. It is deprecated and scheduled for removal in CodeIgniter 3.1+.

: This function is still available, but you're strongly encouraged to remove its usage sooner rather than later.

File helper `read_file()`

File Helper function `read_file()` is now just an alias for PHP's native `file_get_contents()` function. It is deprecated and scheduled for removal in CodeIgniter 3.1+.

: This function is still available, but you're strongly encouraged to remove its usage sooner rather than later.

String helper `repeater()`

String Helper function `repeater()` is now just an alias for PHP's native `str_repeat()` function. It is deprecated and scheduled for removal in CodeIgniter 3.1+.

: This function is still available, but you're strongly encouraged to remove its usage sooner rather than later.

String helper `trim_slashes()`

String Helper function `trim_slashes()` is now just an alias for PHP's native `trim()` function (with a slash passed as its second argument). It is deprecated and scheduled for removal in CodeIgniter 3.1+.

: This function is still available, but you're strongly encouraged to remove its usage sooner rather than later.

Email helper functions

Email Helper only has two functions

- `valid_email()`
- `send_email()`

Both of them are now aliases for PHP's native `filter_var()` and `mail()` functions, respectively. Therefore the *Email Helper* altogether is being deprecated and is scheduled for removal in CodeIgniter 3.1+.

: These functions are still available, but you're strongly encouraged to remove their usage sooner rather than later.

Date helper `standard_date()`

Date Helper function `standard_date()` is being deprecated due to the availability of native PHP [constants](#), which when combined with `date()` provide the same functionality. Furthermore, they have the exact same names as the ones supported by `standard_date()`. Here are examples of how to replace its usage:

```
// Old way
standard_date(); // defaults to standard_date('DATE_RFC822', now());

// Replacement
date('DATE_RFC822', now());

// Old way
standard_date('DATE_ATOM', $time);

// Replacement
date('DATE_ATOM', $time);
```

: This function is still available, but you're strongly encouraged to remove its usage sooner rather than later as it is scheduled for removal in CodeIgniter 3.1+.

Pagination library 'anchor_class' setting

The *Pagination Library* now supports adding pretty much any HTML attribute to your anchors via the 'attributes' configuration setting. This includes passing the 'class' attribute and using the separate 'anchor_class' setting no longer makes sense. As a result of that, the 'anchor_class' setting is now deprecated and scheduled for removal in CodeIgniter 3.1+.

: This setting is still available, but you're strongly encouraged to remove its usage sooner rather than later.

String helper `random_string()` types 'unique' and 'encrypt'

When using the *String Helper* function `random_string()`, you should no longer pass the **unique** and **encrypt** randomization types. They are only aliases for **md5** and **sha1** respectively and are now deprecated and scheduled for removal in CodeIgniter 3.1+.

: These options are still available, but you're strongly encouraged to remove their usage sooner rather than later.

URL helper `url_title()` separators 'dash' and 'underscore'

When using the *URL Helper* function `url_title()`, you should no longer pass **dash** or **underscore** as the word separator. This function will now accept any character and you should just pass the chosen character directly, so you should write '-' instead of 'dash' and '_' instead of 'underscore'.

dash and **underscore** now act as aliases and are deprecated and scheduled for removal in CodeIgniter 3.1+.

: These options are still available, but you're strongly encouraged to remove their usage sooner rather than later.

Database Forge method `add_column()` with an AFTER clause

If you have used the **third parameter** for *Database Forge* method `add_column()` to add a field for an AFTER clause, then you should change its usage.

That third parameter has been deprecated and scheduled for removal in CodeIgniter 3.1+.

You should now put AFTER clause field names in the field definition array instead:

```
// Old usage:
$field = array(
    'new_field' => array('type' => 'TEXT')
);

$this->dbforge->add_column('table_name', $field, 'another_field');
```

```
// New usage:
$field = array(
    'new_field' => array('type' => 'TEXT', 'after' => 'another_field')
);

$this->dbforge->add_column('table_name', $field);
```

: The parameter is still available, but you're strongly encouraged to remove its usage sooner rather than later.

: This is for MySQL and CUBRID databases only! Other drivers don't support this clause and will silently ignore it.

URI Routing methods `fetch_directory()`, `fetch_class()`, `fetch_method()`

With properties `CI_Router::$directory`, `CI_Router::$class` and `CI_Router::$method` being public and their respective `fetch_*()` no longer doing anything else to just return the properties - it doesn't make sense to keep them.

Those are all internal, undocumented methods, but we've opted to deprecate them for now in order to maintain backwards-compatibility just in case. If some of you have utilized them, then you can now just access the properties instead:

```
$this->router->directory;
$this->router->class;
$this->router->method;
```

: Those methods are still available, but you're strongly encouraged to remove their usage sooner rather than later.

Input library method `is_cli_request()`

Calls to the `CI_Input::is_cli_request()` method are necessary at many places in the CodeIgniter internals and this is often before the *Input Library* is loaded. Because of that, it is being replaced by a common function named `is_cli()` and this method is now just an alias.

The new function is both available at all times for you to use and shorter to type.

```
// Old
$this->input->is_cli_request();

// New
is_cli();
```

`CI_Input::is_cli_request()` is now now deprecated and scheduled for removal in CodeIgniter 3.1+.

: This method is still available, but you're strongly encouraged to remove its usage sooner rather than later.

10.11.31 Upgrading From Beta 1.0 to Beta 1.1

To upgrade to Beta 1.1 please perform the following steps:

Step 1: Replace your index file

Replace your main `index.php` file with the new `index.php` file. Note: If you have renamed your “system” folder you will need to edit this info in the new file.

Step 2: Relocate your config folder

This version of CodeIgniter now permits multiple sets of “applications” to all share a common set of backend files. In order to enable each application to have its own configuration values, the config directory must now reside inside of your application folder, so please move it there.

Step 3: Replace directories

Replace the following directories with the new versions:

- drivers
- helpers
- init
- libraries
- scaffolding

Step 4: Add the calendar language file

There is a new language file corresponding to the new calendaring class which must be added to your language folder. Add the following item to your version: `language/english/calendar_lang.php`

Step 5: Edit your config file

The original application/config/config.php file has a typo in it. Open the file and look for the items related to cookies:

```
$conf['cookie_prefix'] = "";
$conf['cookie_domain'] = "";
$conf['cookie_path']   = "/";
```

Change the array name from \$conf to \$config, like this:

```
$config['cookie_prefix'] = "";
$config['cookie_domain'] = "";
$config['cookie_path']   = "/";
```

Lastly, add the following new item to the config file (and edit the option if needed):

```
/*
|-----
| URI PROTOCOL
|-----
|
| This item determines which server global
| should be used to retrieve the URI string. The
| default setting of "auto" works for most servers.
| If your links do not seem to work, try one of
| the other delicious flavors:
|
| 'auto'           Default - auto detects
| 'path_info'      Uses the PATH_INFO
| 'query_string'   Uses the QUERY_STRING
*/

$config['uri_protocol'] = "auto";
```

10.11.32 Upgrading From a Previous Version

Please read the upgrade notes corresponding to the version you are upgrading from.

- *Upgrading from 2.1.4 to 3.0.0*
- *Upgrading from 2.1.3 to 2.1.4*
- *Upgrading from 2.1.2 to 2.1.3*
- *Upgrading from 2.1.1 to 2.1.2*
- *Upgrading from 2.1.0 to 2.1.1*
- *Upgrading from 2.0.3 to 2.1.0*
- *Upgrading from 2.0.2 to 2.0.3*
- *Upgrading from 2.0.1 to 2.0.2*
- *Upgrading from 2.0 to 2.0.1*
- *Upgrading from 1.7.2 to 2.0*
- *Upgrading from 1.7.1 to 1.7.2*
- *Upgrading from 1.7.0 to 1.7.1*

- *Upgrading from 1.6.3 to 1.7.0*
- *Upgrading from 1.6.2 to 1.6.3*
- *Upgrading from 1.6.1 to 1.6.2*
- *Upgrading from 1.6.0 to 1.6.1*

10.12 General Topics

10.12.1 CodeIgniter URLs

By default, URLs in CodeIgniter are designed to be search-engine and human friendly. Rather than using the standard “query string” approach to URLs that is synonymous with dynamic systems, CodeIgniter uses a **segment-based** approach:

```
example.com/news/article/my_article
```

: Query string URLs can be optionally enabled, as described below.

URI Segments

The segments in the URL, in following with the Model-View-Controller approach, usually represent:

```
example.com/class/function/ID
```

1. The first segment represents the controller **class** that should be invoked.
2. The second segment represents the class **function**, or method, that should be called.
3. The third, and any additional segments, represent the ID and any variables that will be passed to the controller.

The *URI Library* and the *URL Helper* contain functions that make it easy to work with your URI data. In addition, your URLs can be remapped using the *URI Routing* feature for more flexibility.

Removing the index.php file

By default, the **index.php** file will be included in your URLs:

```
example.com/index.php/news/article/my_article
```

If your Apache server has *mod_rewrite* enabled, you can easily remove this file by using a *.htaccess* file with some simple rules. Here is an example of such a file, using the “negative” method in which everything is redirected except the specified items:

```
RewriteEngine On
RewriteCond %{REQUEST_FILENAME} !-f
RewriteCond %{REQUEST_FILENAME} !-d
RewriteRule ^(.*)$ index.php/$1 [L]
```

In the above example, any HTTP request other than those for existing directories and existing files is treated as a request for your *index.php* file.

: These specific rules might not work for all server configurations.

: Make sure to also exclude from the above rule any assets that you might need to be accessible from the outside world.

Adding a URL Suffix

In your **config/config.php** file you can specify a suffix that will be added to all URLs generated by CodeIgniter. For example, if a URL is this:

```
example.com/index.php/products/view/shoes
```

You can optionally add a suffix, like **.html**, making the page appear to be of a certain type:

```
example.com/index.php/products/view/shoes.html
```

Enabling Query Strings

In some cases you might prefer to use query strings URLs:

```
index.php?c=products&m=view&id=345
```

CodeIgniter optionally supports this capability, which can be enabled in your **application/config.php** file. If you open your config file you’ll see these items:

```
$config['enable_query_strings'] = FALSE;
$config['controller_trigger'] = 'c';
$config['function_trigger'] = 'm';
```

If you change “enable_query_strings” to TRUE this feature will become active. Your controllers and functions will then be accessible using the “trigger” words you’ve set to invoke your controllers and methods:

```
index.php?c=controller&m=method
```

: If you are using query strings you will have to build your own URLs, rather than utilizing the URL helpers (and other helpers that generate URLs, like some of the form helpers) as these are designed to work with segment based URLs.

10.12.2 Controllers

Controllers are the heart of your application, as they determine how HTTP requests should be handled.

 - What is a Controller?
 - Let's try it: Hello World!
 - Methods
 - Passing URI Segments to your methods
 - Defining a Default Controller
 - Remapping Method Calls
 - Processing Output
 - Private methods
 - Organizing Your Controllers into Sub-directories
 - Class Constructors
 - Reserved method names
 - That's it!

What is a Controller?

A Controller is simply a class file that is named in a way that can be associated with a URI.

Consider this URI:

```
example.com/index.php/blog/
```

In the above example, CodeIgniter would attempt to find a controller named Blog.php and load it.

When a controller's name matches the first segment of a URI, it will be loaded.

Let's try it: Hello World!

Let's create a simple controller so you can see it in action. Using your text editor, create a file called Blog.php, and put the following code in it:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        echo 'Hello World!';
    }

}
```

Then save the file to your *application/controllers/* directory.

: The file must be called 'Blog.php', with a capital 'B'.

Now visit the your site using a URL similar to this:

```
example.com/index.php/blog/
```

If you did it right, you should see:

Hello World!

: Class names must start with an uppercase letter.

This is valid:

```
<?php
class Blog extends CI_Controller {

}
```

This is **not** valid:

```
<?php
class blog extends CI_Controller {

}
```

Also, always make sure your controller extends the parent controller class so that it can inherit all its methods.

Methods

In the above example the method name is `index()`. The “index” method is always loaded by default if the **second segment** of the URI is empty. Another way to show your “Hello World” message would be this:

`example.com/index.php/blog/index/`

The second segment of the URI determines which method in the controller gets called.

Let’s try it. Add a new method to your controller:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        echo 'Hello World!';
    }

    public function comments()
    {
        echo 'Look at this!';
    }

}
```

Now load the following URL to see the comment method:

`example.com/index.php/blog/comments/`

You should see your new message.

Passing URI Segments to your methods

If your URI contains more than two segments they will be passed to your method as parameters.

For example, let’s say you have a URI like this:

example.com/index.php/products/shoes/sandals/123

Your method will be passed URI segments 3 and 4 (“sandals” and “123”):

```
<?php
class Products extends CI_Controller {

    public function shoes($sandals, $id)
    {
        echo $sandals;
        echo $id;
    }
}
```

: If you are using the *URI Routing* feature, the segments passed to your method will be the re-routed ones.

Defining a Default Controller

CodeIgniter can be told to load a default controller when a URI is not present, as will be the case when only your site root URL is requested. To specify a default controller, open your **application/config/routes.php** file and set this variable:

```
$route['default_controller'] = 'Blog';
```

Where Blog is the name of the controller class you want used. If you now load your main index.php file without specifying any URI segments you’ll see your Hello World message by default.

Remapping Method Calls

As noted above, the second segment of the URI typically determines which method in the controller gets called. CodeIgniter permits you to override this behavior through the use of the `_remap()` method:

```
public function _remap()
{
    // Some code here...
}
```

: If your controller contains a method named `_remap()`, it will **always** get called regardless of what your URI contains. It overrides the normal behavior in which the URI determines which method is called, allowing you to define your own method routing rules.

The overridden method call (typically the second segment of the URI) will be passed as a parameter to the `_remap()` method:

```
public function _remap($method)
{
    if ($method === 'some_method')
    {
        $this->$method();
    }
    else
    {
        $this->default_method();
    }
}
```

Any extra segments after the method name are passed into `_remap()` as an optional second parameter. This array can be used in combination with PHP's `call_user_func_array()` to emulate CodeIgniter's default behavior.

Example:

```
public function _remap($method, $params = array())
{
    $method = 'process_'.$method;
    if (method_exists($this, $method))
    {
        return call_user_func_array(array($this, $method), $params);
    }
    show_404();
}
```

Processing Output

CodeIgniter has an output class that takes care of sending your final rendered data to the web browser automatically. More information on this can be found in the *Views* and *Output Class* pages. In some cases, however, you might want to post-process the finalized data in some way and send it to the browser yourself. CodeIgniter permits you to add a method named `_output()` to your controller that will receive the finalized output data.

: If your controller contains a method named `_output()`, it will **always** be called by the output class instead of echoing the finalized data directly. The first parameter of the method will contain the finalized output.

Here is an example:

```
public function _output($output)
{
    echo $output;
}
```

: Please note that your `_output()` method will receive the data in its finalized state. Benchmark and memory usage data will be rendered, cache files written (if you have caching enabled), and headers will be sent (if you use that *feature*) before it is handed off to the `_output()` method. To have your controller's output cached properly, its `_output()` method can use:

```
if ($this->output->cache_expiration > 0)
{
    $this->output->_write_cache($output);
}
```

If you are using this feature the page execution timer and memory usage stats might not be perfectly accurate since they will not take into account any further processing you do. For an alternate way to control output *before* any of the final processing is done, please see the available methods in the *Output Library*.

Private methods

In some cases you may want certain methods hidden from public access. In order to achieve this, simply declare the method as being private or protected and it will not be served via a URL request. For example, if you were to have a method like this:

```
private function _utility()
{
```

```
// some code  
}
```

Trying to access it via the URL, like this, will not work:

```
example.com/index.php/blog/_utility/
```

: Prefixing method names with an underscore will also prevent them from being called. This is a legacy feature that is left for backwards-compatibility.

Organizing Your Controllers into Sub-directories

If you are building a large application you might find it convenient to organize your controllers into sub-directories. CodeIgniter permits you to do this.

Simply create folders within your *application/controllers/* directory and place your controller classes within them.

: When using this feature the first segment of your URI must specify the folder. For example, let's say you have a controller located here:

```
application/controllers/products/Shoes.php
```

To call the above controller your URI will look something like this:

```
example.com/index.php/products/shoes/show/123
```

Each of your sub-directories may contain a default controller which will be called if the URL contains only the sub-folder. Simply name your default controller as specified in your *application/config/routes.php* file.

CodeIgniter also permits you to remap your URIs using its *URI Routing* feature.

Class Constructors

If you intend to use a constructor in any of your Controllers, you **MUST** place the following line of code in it:

```
parent::__construct();
```

The reason this line is necessary is because your local constructor will be overriding the one in the parent controller class so we need to manually call it.

Example:

```
<?php  
class Blog extends CI_Controller {  
  
    public function __construct()  
    {  
        parent::__construct();  
        // Your own constructor code  
    }  
}
```

Constructors are useful if you need to set some default values, or run a default process when your class is instantiated. Constructors can't return a value, but they can do some default work.

Reserved method names

Since your controller classes will extend the main application controller you must be careful not to name your methods identically to the ones used by that class, otherwise your local functions will override them. See *Reserved Names* for a full list.

: You should also never have a method named identically to its class name. If you do, and there is no `__construct()` method in the same class, then your e.g. `Index::index()` method will be executed as a class constructor! This is a PHP4 backwards-compatibility feature.

That's it!

That, in a nutshell, is all there is to know about controllers.

10.12.3 Reserved Names

In order to help out, CodeIgniter uses a series of function, method, class and variable names in its operation. Because of this, some names cannot be used by a developer. Following is a list of reserved names that cannot be used.

Controller names

Since your controller classes will extend the main application controller you must be careful not to name your methods identically to the ones used by that class, otherwise your local methods will override them. The following is a list of reserved names. Do not name your controller any of these:

- Controller
- CI_Base
- _ci_initialize
- Default
- index

Functions

- `is_php()`
- `is_really_writable()`
- `load_class()`
- `is_loaded()`
- `get_config()`
- `config_item()`
- `show_error()`
- `show_404()`
- `log_message()`
- `set_status_header()`
- `get_mimes()`

- `html_escape()`
- `remove_invisible_characters()`
- `is_https()`
- `function_usable()`
- `get_instance()`
- `_exception_handler()`
- `_stringify_attributes()`

Variables

- `$config`
- `$db`
- `$lang`

Constants

- `ENVIRONMENT`
- `FCPATH`
- `SELF`
- `BASEPATH`
- `APPPATH`
- `VIEWPATH`
- `CI_VERSION`
- `FILE_READ_MODE`
- `FILE_WRITE_MODE`
- `DIR_READ_MODE`
- `DIR_WRITE_MODE`
- `FOPEN_READ`
- `FOPEN_READ_WRITE`
- `FOPEN_WRITE_CREATE_DESTRUCTIVE`
- `FOPEN_READ_WRITE_CREATE_DESTRUCTIVE`
- `FOPEN_WRITE_CREATE`
- `FOPEN_READ_WRITE_CREATE`
- `FOPEN_WRITE_CREATE_STRICT`
- `FOPEN_READ_WRITE_CREATE_STRICT`
- `EXIT_SUCCESS`
- `EXIT_ERROR`
- `EXIT_CONFIG`

- EXIT_UNKNOWN_FILE
- EXIT_UNKNOWN_CLASS
- EXIT_UNKNOWN_METHOD
- EXIT_USER_INPUT
- EXIT_DATABASE
- EXIT__AUTO_MIN
- EXIT__AUTO_MAX

10.12.4 Views

A view is simply a web page, or a page fragment, like a header, footer, sidebar, etc. In fact, views can flexibly be embedded within other views (within other views, etc., etc.) if you need this type of hierarchy.

Views are never called directly, they must be loaded by a *controller*. Remember that in an MVC framework, the Controller acts as the traffic cop, so it is responsible for fetching a particular view. If you have not read the *Controllers* page you should do so before continuing.

Using the example controller you created in the *controller* page, let's add a view to it.

Creating a View

Using your text editor, create a file called `blogview.php`, and put this in it:

```
<html>
<head>
    <title>My Blog</title>
</head>
<body>
    <h1>Welcome to my Blog!</h1>
</body>
</html>
```

Then save the file in your *application/views/* directory.

Loading a View

To load a particular view file you will use the following method:

```
$this->load->view('name');
```

Where `name` is the name of your view file.

: The `.php` file extension does not need to be specified unless you use something other than `.php`.

Now, open the controller file you made earlier called `Blog.php`, and replace the `echo` statement with the view loading method:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
```

```
        $this->load->view('blogview');  
    }  
}
```

If you visit your site using the URL you did earlier you should see your new view. The URL was similar to this:

`example.com/index.php/blog/`

Loading multiple views

CodeIgniter will intelligently handle multiple calls to `$this->load->view()` from within a controller. If more than one call happens they will be appended together. For example, you may wish to have a header view, a menu view, a content view, and a footer view. That might look something like this:

```
<?php  
  
class Page extends CI_Controller {  
  
    public function index()  
    {  
        $data['page_title'] = 'Your title';  
        $this->load->view('header');  
        $this->load->view('menu');  
        $this->load->view('content', $data);  
        $this->load->view('footer');  
    }  
}
```

In the example above, we are using “dynamically added data”, which you will see below.

Storing Views within Sub-directories

Your view files can also be stored within sub-directories if you prefer that type of organization. When doing so you will need to include the directory name loading the view. Example:

```
$this->load->view('directory_name/file_name');
```

Adding Dynamic Data to the View

Data is passed from the controller to the view by way of an **array** or an **object** in the second parameter of the view loading method. Here is an example using an array:

```
$data = array(  
    'title' => 'My Title',  
    'heading' => 'My Heading',  
    'message' => 'My Message'  
);  
  
$this->load->view('blogview', $data);
```

And here's an example using an object:

```
$data = new Someclass();  
$this->load->view('blogview', $data);
```

: If you use an object, the class variables will be turned into array elements.

Let's try it with your controller file. Open it add this code:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        $data['title'] = "My Real Title";
        $data['heading'] = "My Real Heading";

        $this->load->view('blogview', $data);
    }
}
```

Now open your view file and change the text to variables that correspond to the array keys in your data:

```
<html>
<head>
    <title><?php echo $title;?></title>
</head>
<body>
    <h1><?php echo $heading;?></h1>
</body>
</html>
```

Then load the page at the URL you've been using and you should see the variables replaced.

Creating Loops

The data array you pass to your view files is not limited to simple variables. You can pass multi dimensional arrays, which can be looped to generate multiple rows. For example, if you pull data from your database it will typically be in the form of a multi-dimensional array.

Here's a simple example. Add this to your controller:

```
<?php
class Blog extends CI_Controller {

    public function index()
    {
        $data['todo_list'] = array('Clean House', 'Call Mom', 'Run Errands');

        $data['title'] = "My Real Title";
        $data['heading'] = "My Real Heading";

        $this->load->view('blogview', $data);
    }
}
```

Now open your view file and create a loop:

```
<html>
<head>
    <title><?php echo $title;?></title>
</head>
<body>
```

```
<h1><?php echo $heading;?></h1>

<h3>My Todo List</h3>

<ul>
<?php foreach ($todo_list as $item):?>

    <li><?php echo $item;?></li>

<?php endforeach;?>
</ul>

</body>
</html>
```

: You'll notice that in the example above we are using PHP's alternative syntax. If you are not familiar with it you can read about it *here*.

Returning views as data

There is a third **optional** parameter lets you change the behavior of the method so that it returns data as a string rather than sending it to your browser. This can be useful if you want to process the data in some way. If you set the parameter to TRUE (boolean) it will return data. The default behavior is false, which sends it to your browser. Remember to assign it to a variable if you want the data returned:

```
$string = $this->load->view('myfile', '', TRUE);
```

10.12.5 Models

Models are **optionally** available for those who want to use a more traditional MVC approach.

Page Contents

- Models
 - What is a Model?
 - Anatomy of a Model
 - Loading a Model
 - Auto-loading Models
 - Connecting to your Database

What is a Model?

Models are PHP classes that are designed to work with information in your database. For example, let's say you use CodeIgniter to manage a blog. You might have a model class that contains functions to insert, update, and retrieve your blog data. Here is an example of what such a model class might look like:

```
class Blog_model extends CI_Model {

    public $title;
    public $content;
    public $date;
```

```

public function __construct()
{
    // Call the CI_Model constructor
    parent::__construct();
}

public function get_last_ten_entries()
{
    $query = $this->db->get('entries', 10);
    return $query->result();
}

public function insert_entry()
{
    $this->title    = $_POST['title']; // please read the below note
    $this->content  = $_POST['content'];
    $this->date     = time();

    $this->db->insert('entries', $this);
}

public function update_entry()
{
    $this->title    = $_POST['title'];
    $this->content  = $_POST['content'];
    $this->date     = time();

    $this->db->update('entries', $this, array('id' => $_POST['id']));
}
}

```

: The methods in the above example use the *Query Builder* database methods.

: For the sake of simplicity in this example we're using `$_POST` directly. This is generally bad practice, and a more common approach would be to use the *Input Library* `$this->input->post('title')`.

Anatomy of a Model

Model classes are stored in your **application/models/** directory. They can be nested within sub-directories if you want this type of organization.

The basic prototype for a model class is this:

```

class Model_name extends CI_Model {

    public function __construct()
    {
        parent::__construct();
    }

}

```

Where **Model_name** is the name of your class. Class names **must** have the first letter capitalized with the rest of the name lowercase. Make sure your class extends the base Model class.

The file name must match the class name. For example, if this is your class:

```
class User_model extends CI_Model {

    public function __construct()
    {
        parent::__construct();
    }

}
```

Your file will be this:

```
application/models/User_model.php
```

Loading a Model

Your models will typically be loaded and called from within your *controller* methods. To load a model you will use the following method:

```
$this->load->model('model_name');
```

If your model is located in a sub-directory, include the relative path from your models directory. For example, if you have a model located at *application/models/blog/Queries.php* you'll load it using:

```
$this->load->model('blog/queries');
```

Once loaded, you will access your model methods using an object with the same name as your class:

```
$this->load->model('model_name');
```

```
$this->model_name->method();
```

If you would like your model assigned to a different object name you can specify it via the second parameter of the loading method:

```
$this->load->model('model_name', 'foobar');
```

```
$this->foobar->method();
```

Here is an example of a controller, that loads a model, then serves a view:

```
class Blog_controller extends CI_Controller {

    public function blog()
    {
        $this->load->model('blog');

        $data['query'] = $this->Blog->get_last_ten_entries();

        $this->load->view('blog', $data);
    }

}
```

Auto-loading Models

If you find that you need a particular model globally throughout your application, you can tell CodeIgniter to auto-load it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the

model to the autoload array.

Connecting to your Database

When a model is loaded it does **NOT** connect automatically to your database. The following options for connecting are available to you:

- You can connect using the standard database methods *described here*, either from within your Controller class or your Model class.
- You can tell the model loading method to auto-connect by passing TRUE (boolean) via the third parameter, and connectivity settings, as defined in your database config file will be used:

```
$this->load->model('model_name', '', TRUE);
```

- You can manually pass database connectivity settings via the third parameter:

```
$config['hostname'] = 'localhost';
$config['username'] = 'myusername';
$config['password'] = 'mypassword';
$config['database'] = 'mydatabase';
$config['dbdriver'] = 'mysqli';
$config['dbprefix'] = '';
$config['pconnect'] = FALSE;
$config['db_debug'] = TRUE;

$this->load->model('model_name', '', $config);
```

10.12.6 Helper Functions

Helpers, as the name suggests, help you with tasks. Each helper file is simply a collection of functions in a particular category. There are **URL Helpers**, that assist in creating links, there are Form Helpers that help you create form elements, **Text Helpers** perform various text formatting routines, **Cookie Helpers** set and read cookies, File Helpers help you deal with files, etc.

Unlike most other systems in CodeIgniter, Helpers are not written in an Object Oriented format. They are simple, procedural functions. Each helper function performs one specific task, with no dependence on other functions.

CodeIgniter does not load Helper Files by default, so the first step in using a Helper is to load it. Once loaded, it becomes globally available in your *controller* and *views*.

Helpers are typically stored in your **system/helpers**, or **application/helpers directory**. CodeIgniter will look first in your **application/helpers directory**. If the directory does not exist or the specified helper is not located there CI will instead look in your global *system/helpers/* directory.

Loading a Helper

Loading a helper file is quite simple using the following method:

```
$this->load->helper('name');
```

Where **name** is the file name of the helper, without the .php file extension or the “helper” part.

For example, to load the **URL Helper** file, which is named **url_helper.php**, you would do this:

```
$this->load->helper('url');
```

A helper can be loaded anywhere within your controller methods (or even within your View files, although that's not a good practice), as long as you load it before you use it. You can load your helpers in your controller constructor so that they become available automatically in any function, or you can load a helper in a specific function that needs it.

: The Helper loading method above does not return a value, so don't try to assign it to a variable. Just use it as shown.

Loading Multiple Helpers

If you need to load more than one helper you can specify them in an array, like this:

```
$this->load->helper(
    array('helper1', 'helper2', 'helper3')
);
```

Auto-loading Helpers

If you find that you need a particular helper globally throughout your application, you can tell CodeIgniter to auto-load it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the helper to the autoload array.

Using a Helper

Once you've loaded the Helper File containing the function you intend to use, you'll call it the way you would a standard PHP function.

For example, to create a link using the `anchor()` function in one of your view files you would do this:

```
<?php echo anchor('blog/comments', 'Click Here');?>
```

Where "Click Here" is the name of the link, and "blog/comments" is the URI to the controller/method you wish to link to.

"Extending" Helpers

To "extend" Helpers, create a file in your **application/helpers/** folder with an identical name to the existing Helper, but prefixed with **MY_** (this item is configurable. See below.).

If all you need to do is add some functionality to an existing helper - perhaps add a function or two, or change how a particular helper function operates - then it's overkill to replace the entire helper with your version. In this case it's better to simply "extend" the Helper.

: The term "extend" is used loosely since Helper functions are procedural and discrete and cannot be extended in the traditional programmatic sense. Under the hood, this gives you the ability to add to or to replace the functions a Helper provides.

For example, to extend the native **Array Helper** you'll create a file named **application/helpers/MY_array_helper.php**, and add or override functions:

```
// any_in_array() is not in the Array Helper, so it defines a new function
function any_in_array($needle, $haystack)
{
    $needle = is_array($needle) ? $needle : array($needle);
```

```

        foreach ($needle as $item)
        {
            if (in_array($item, $haystack))
            {
                return TRUE;
            }
        }

        return FALSE;
    }

    // random_element() is included in Array Helper, so it overrides the native function
    function random_element($array)
    {
        shuffle($array);
        return array_pop($array);
    }

```

Setting Your Own Prefix

The filename prefix for “extending” Helpers is the same used to extend libraries and core classes. To set your own prefix, open your **application/config/config.php** file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with **CI_** so DO NOT use that as your prefix.

Now What?

In the Table of Contents you’ll find a list of all the available Helper Files. Browse each one to see what they do.

10.12.7 Using CodeIgniter Libraries

All of the available libraries are located in your *system/libraries/* directory. In most cases, to use one of these classes involves initializing it within a *controller* using the following initialization method:

```
$this->load->library('class_name');
```

Where ‘class_name’ is the name of the class you want to invoke. For example, to load the *Form Validation Library* you would do this:

```
$this->load->library('form_validation');
```

Once initialized you can use it as indicated in the user guide page corresponding to that class.

Additionally, multiple libraries can be loaded at the same time by passing an array of libraries to the load method.

Example:

```
$this->load->library(array('email', 'table'));
```

Creating Your Own Libraries

Please read the section of the user guide that discusses how to *create your own libraries*.

10.12.8 Creating Libraries

When we use the term “Libraries” we are normally referring to the classes that are located in the libraries directory and described in the Class Reference of this user guide. In this case, however, we will instead describe how you can create your own libraries within your *application/libraries* directory in order to maintain separation between your local resources and the global framework resources.

As an added bonus, CodeIgniter permits your libraries to extend native classes if you simply need to add some functionality to an existing library. Or you can even replace native libraries just by placing identically named versions in your *application/libraries* directory.

In summary:

- You can create entirely new libraries.
- You can extend native libraries.
- You can replace native libraries.

The page below explains these three concepts in detail.

: The Database classes can not be extended or replaced with your own classes. All other classes are able to be replaced/extended.

Storage

Your library classes should be placed within your *application/libraries* directory, as this is where CodeIgniter will look for them when they are initialized.

Naming Conventions

- File names must be capitalized. For example: Myclass.php
- Class declarations must be capitalized. For example: class Myclass
- Class names and file names must match.

The Class File

Classes should have this basic prototype:

```
<?php if ( ! defined('BASEPATH')) exit('No direct script access allowed');

class Someclass {

    public function some_method()
    {
    }

}

/* End of file Someclass.php */
```

: We are using the name Someclass purely as an example.

Using Your Class

From within any of your *Controller* methods you can initialize your class using the standard:

```
$this->load->library('someclass');
```

Where *someclass* is the file name, without the ".php" file extension. You can submit the file name capitalized or lower case. CodeIgniter doesn't care.

Once loaded you can access your class using the lower case version:

```
$this->someclass->some_method(); // Object instances will always be lower case
```

Passing Parameters When Initializing Your Class

In the library loading method you can dynamically pass data as an array via the second parameter and it will be passed to your class constructor:

```
$params = array('type' => 'large', 'color' => 'red');

$this->load->library('someclass', $params);
```

If you use this feature you must set up your class constructor to expect data:

```
<?php defined('BASEPATH') OR exit('No direct script access allowed');

class Someclass {

    public function __construct($params)
    {
        // Do something with $params
    }
}
```

You can also pass parameters stored in a config file. Simply create a config file named identically to the class file name and store it in your *application/config/* directory. Note that if you dynamically pass parameters as described above, the config file option will not be available.

Utilizing CodeIgniter Resources within Your Library

To access CodeIgniter's native resources within your library use the `get_instance()` method. This method returns the CodeIgniter super object.

Normally from within your controller methods you will call any of the available CodeIgniter methods using the `$this` construct:

```
$this->load->helper('url');
$this->load->library('session');
$this->config->item('base_url');
// etc.
```

`$this`, however, only works directly within your controllers, your models, or your views. If you would like to use CodeIgniter's classes from within your own custom classes you can do so as follows:

First, assign the CodeIgniter object to a variable:

```
$CI =& get_instance();
```

Once you've assigned the object to a variable, you'll use that variable *instead* of `$this`:

```
$CI =& get_instance();

$CI->load->helper('url');
$CI->load->library('session');
$CI->config->item('base_url');
// etc.
```

: You'll notice that the above `get_instance()` function is being passed by reference:

```
$CI =& get_instance();
```

This is very important. Assigning by reference allows you to use the original CodeIgniter object rather than creating a copy of it.

However, since a library is a class, it would be better if you take full advantage of the OOP principles. So, in order to be able to use the CodeIgniter super-object in all of the class methods, you're encouraged to assign it to a property instead:

```
class Example_library {

    protected $CI;

    // We'll use a constructor, as you can't directly call a function
    // from a property definition.
    public function __construct()
    {
        // Assign the CodeIgniter super-object
        $this->CI =& get_instance();
    }

    public function foo()
    {
        $this->CI->load->helper('url');
        redirect();
    }

    public function bar()
    {
        echo $this->CI->config_item('base_url');
    }

}
```

Replacing Native Libraries with Your Versions

Simply by naming your class files identically to a native library will cause CodeIgniter to use it instead of the native one. To use this feature you must name the file and the class declaration exactly the same as the native library. For example, to replace the native Email library you'll create a file named *application/libraries/Email.php*, and declare your class with:

```
class CI_Email {

}
```

Note that most native classes are prefixed with `CI_`.

To load your library you'll see the standard loading method:

```
$this->load->library('email');
```

: At this time the Database classes can not be replaced with your own versions.

Extending Native Libraries

If all you need to do is add some functionality to an existing library - perhaps add a method or two - then it's overkill to replace the entire library with your version. In this case it's better to simply extend the class. Extending a class is nearly identical to replacing a class with a couple exceptions:

- The class declaration must extend the parent class.
- Your new class name and filename must be prefixed with MY_ (this item is configurable. See below.).

For example, to extend the native Email class you'll create a file named *application/libraries/MY_Email.php*, and declare your class with:

```
class MY_Email extends CI_Email {  
  
}
```

If you need to use a constructor in your class make sure you extend the parent constructor:

```
class MY_Email extends CI_Email {  
  
    public function __construct($config = array())  
    {  
        parent::__construct($config);  
    }  
  
}
```

: Not all of the libraries have the same (or any) parameters in their constructor. Take a look at the library that you're extending first to see how it should be implemented.

Loading Your Sub-class

To load your sub-class you'll use the standard syntax normally used. DO NOT include your prefix. For example, to load the example above, which extends the Email class, you will use:

```
$this->load->library('email');
```

Once loaded you will use the class variable as you normally would for the class you are extending. In the case of the email class all calls will use:

```
$this->email->some_method();
```

Setting Your Own Prefix

To set your own sub-class prefix, open your *application/config/config.php* file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with `CI_` so DO NOT use that as your prefix.

10.12.9 Using CodeIgniter Drivers

Drivers are a special type of Library that has a parent class and any number of potential child classes. Child classes have access to the parent class, but not their siblings. Drivers provide an elegant syntax in your *controllers* for libraries that benefit from or require being broken down into discrete classes.

Drivers are found in the *system/libraries/* directory, in their own sub-directory which is identically named to the parent library class. Also inside that directory is a subdirectory named *drivers*, which contains all of the possible child class files.

To use a driver you will initialize it within a controller using the following initialization method:

```
$this->load->driver('class_name');
```

Where class name is the name of the driver class you want to invoke. For example, to load a driver named “Some_parent” you would do this:

```
$this->load->driver('some_parent');
```

Methods of that class can then be invoked with:

```
$this->some_parent->some_method();
```

The child classes, the drivers themselves, can then be called directly through the parent class, without initializing them:

```
$this->some_parent->child_one->some_method();  
$this->some_parent->child_two->another_method();
```

Creating Your Own Drivers

Please read the section of the user guide that discusses how to *create your own drivers*.

10.12.10 Creating Drivers

Driver Directory and File Structure

Sample driver directory and file structure layout:

- /application/libraries/Driver_name
 - Driver_name.php
 - drivers
 - * Driver_name_subclass_1.php
 - * Driver_name_subclass_2.php
 - * Driver_name_subclass_3.php

: In order to maintain compatibility on case-sensitive file systems, the `Driver_name` directory must be named in the format returned by `ucfirst()`.

10.12.11 Creating Core System Classes

Every time CodeIgniter runs there are several base classes that are initialized automatically as part of the core framework. It is possible, however, to swap any of the core system classes with your own versions or even extend the core versions.

Most users will never have any need to do this, but the option to replace or extend them does exist for those who would like to significantly alter the CodeIgniter core.

: Messing with a core system class has a lot of implications, so make sure you know what you are doing before attempting it.

System Class List

The following is a list of the core system files that are invoked every time CodeIgniter runs:

- Benchmark
- Config
- Controller
- Exceptions
- Hooks
- Input
- Language
- Loader
- Log
- Output
- Router
- Security
- URI
- Utf8

Replacing Core Classes

To use one of your own system classes instead of a default one simply place your version inside your local *application/core/* directory:

```
application/core/some_class.php
```

If this directory does not exist you can create it.

Any file named identically to one from the list above will be used instead of the one normally used.

Please note that your class must use CI as a prefix. For example, if your file is named Input.php the class will be named:

```
class CI_Input {  
  
}
```

Extending Core Class

If all you need to do is add some functionality to an existing library - perhaps add a method or two - then it's overkill to replace the entire library with your version. In this case it's better to simply extend the class. Extending a class is nearly identical to replacing a class with a couple exceptions:

- The class declaration must extend the parent class.
- Your new class name and filename must be prefixed with MY_ (this item is configurable. See below.).

For example, to extend the native Input class you'll create a file named `application/core/MY_Input.php`, and declare your class with:

```
class MY_Input extends CI_Input {  
  
}
```

: If you need to use a constructor in your class make sure you extend the parent constructor:

```
class MY_Input extends CI_Input {  
  
    public function __construct()  
    {  
        parent::__construct();  
    }  
  
}
```

Tip: Any functions in your class that are named identically to the methods in the parent class will be used instead of the native ones (this is known as “method overriding”). This allows you to substantially alter the CodeIgniter core.

If you are extending the Controller core class, then be sure to extend your new class in your application controller's constructors.

```
class Welcome extends MY_Controller {  
  
    public function __construct()  
    {  
        parent::__construct();  
    }  
  
    public function index()  
    {  
        $this->load->view('welcome_message');  
    }  
  
}
```

Setting Your Own Prefix

To set your own sub-class prefix, open your `application/config/config.php` file and look for this item:

```
$config['subclass_prefix'] = 'MY_';
```

Please note that all native CodeIgniter libraries are prefixed with CI_ so DO NOT use that as your prefix.

10.12.12 Creating Ancillary Classes

In some cases you may want to develop classes that exist apart from your controllers but have the ability to utilize all of CodeIgniter's resources. This is easily possible as you'll see.

`get_instance()`

`get_instance()`

object of class `CI_Controller`

Any class that you instantiate within your controller methods can access CodeIgniter's native resources simply by using the `get_instance()` function. This function returns the main CodeIgniter object.

Normally, to call any of the available CodeIgniter methods requires you to use the `$this` construct:

```
$this->load->helper('url');
$this->load->library('session');
$this->config->item('base_url');
// etc.
```

`$this`, however, only works within your controllers, your models, or your views. If you would like to use CodeIgniter's classes from within your own custom classes you can do so as follows:

First, assign the CodeIgniter object to a variable:

```
$CI =& get_instance();
```

Once you've assigned the object to a variable, you'll use that variable *instead* of `$this`:

```
$CI =& get_instance();

$CI->load->helper('url');
$CI->load->library('session');
$CI->config->item('base_url');
// etc.
```

: You'll notice that the above `get_instance()` function is being passed by reference:

```
$CI =& get_instance();
```

This is very important. Assigning by reference allows you to use the original CodeIgniter object rather than creating a copy of it.

Furthermore, if you'll be using `get_instance()` inside another class, then it would be better if you assign it to a property. This way, you won't need to call `get_instance()` in every single method.

Example:

```
class Example {

    protected $CI;

    // We'll use a constructor, as you can't directly call a function
    // from a property definition.
    public function __construct()
    {
        // Assign the CodeIgniter super-object
        $this->CI =& get_instance();
    }
}
```

```
    }

    public function foo()
    {
        $this->CI->load->helper('url');
        redirect();
    }

    public function bar()
    {
        $this->CI->config_item('base_url');
    }
}
```

In the above example, both methods `foo()` and `bar()` will work after you instantiate the `Example` class, without the need to call `get_instance()` in each of them.

10.12.13 Hooks - Extending the Framework Core

CodeIgniter's Hooks feature provides a means to tap into and modify the inner workings of the framework without hacking the core files. When CodeIgniter runs it follows a specific execution process, diagramed in the *Application Flow* page. There may be instances, however, where you'd like to cause some action to take place at a particular stage in the execution process. For example, you might want to run a script right before your controllers get loaded, or right after, or you might want to trigger one of your own scripts in some other location.

Enabling Hooks

The hooks feature can be globally enabled/disabled by setting the following item in the **application/config/config.php** file:

```
$config['enable_hooks'] = TRUE;
```

Defining a Hook

Hooks are defined in **application/config/hooks.php** file. Each hook is specified as an array with this prototype:

```
$hook['pre_controller'] = array(
    'class'      => 'MyClass',
    'function'   => 'Myfunction',
    'filename'   => 'Myclass.php',
    'filepath'   => 'hooks',
    'params'     => array('beer', 'wine', 'snacks')
);
```

Notes:

The array index correlates to the name of the particular hook point you want to use. In the above example the hook point is `pre_controller`. A list of hook points is found below. The following items should be defined in your associative hook array:

- **class** The name of the class you wish to invoke. If you prefer to use a procedural function instead of a class, leave this item blank.
- **function** The function (or method) name you wish to call.

- **filename** The file name containing your class/function.
- **filepath** The name of the directory containing your script. Note: Your script must be located in a directory *INSIDE* your *application/* directory, so the file path is relative to that directory. For example, if your script is located in *application/hooks/*, you will simply use 'hooks' as your filepath. If your script is located in *application/hooks/utilities/* you will use 'hooks/utilities' as your filepath. No trailing slash.
- **params** Any parameters you wish to pass to your script. This item is optional.

Multiple Calls to the Same Hook

If want to use the same hook point with more then one script, simply make your array declaration multi-dimensional, like this:

```
$hook['pre_controller'][] = array(
    'class'      => 'MyClass',
    'function'   => 'MyMethod',
    'filename'   => 'Myclass.php',
    'filepath'   => 'hooks',
    'params'     => array('beer', 'wine', 'snacks')
);

$hook['pre_controller'][] = array(
    'class'      => 'MyOtherClass',
    'function'   => 'MyOtherMethod',
    'filename'   => 'Myotherclass.php',
    'filepath'   => 'hooks',
    'params'     => array('red', 'yellow', 'blue')
);
```

Notice the brackets after each array index:

```
$hook['pre_controller'] []
```

This permits you to have the same hook point with multiple scripts. The order you define your array will be the execution order.

Hook Points

The following is a list of available hook points.

- **pre_system** Called very early during system execution. Only the benchmark and hooks class have been loaded at this point. No routing or other processes have happened.
- **pre_controller** Called immediately prior to any of your controllers being called. All base classes, routing, and security checks have been done.
- **post_controller_constructor** Called immediately after your controller is instantiated, but prior to any method calls happening.
- **post_controller** Called immediately after your controller is fully executed.
- **display_override** Overrides the `_display()` method, used to send the finalized page to the web browser at the end of system execution. This permits you to use your own display methodology. Note that you will need to reference the CI superobject with `$this->CI =& get_instance()` and then the finalized data will be available by calling `$this->CI->output->get_output()`.
- **cache_override** Enables you to call your own method instead of the `_display_cache()` method in the *Output Library*. This permits you to use your own cache display mechanism.

- **post_system** Called after the final rendered page is sent to the browser, at the end of system execution after the finalized data is sent to the browser.

10.12.14 Auto-loading Resources

CodeIgniter comes with an “Auto-load” feature that permits libraries, helpers, and models to be initialized automatically every time the system runs. If you need certain resources globally throughout your application you should consider auto-loading them for convenience.

The following items can be loaded automatically:

- Classes found in the *libraries/* directory
- Helper files found in the *helpers/* directory
- Custom config files found in the *config/* directory
- Language files found in the *system/language/* directory
- Models found in the *models/* folder

To autoload resources, open the **application/config/autoload.php** file and add the item you want loaded to the autoload array. You’ll find instructions in that file corresponding to each type of item.

: Do not include the file extension (.php) when adding items to the autoload array.

10.12.15 Common Functions

CodeIgniter uses a few functions for its operation that are globally defined, and are available to you at any point. These do not require loading any libraries or helpers.

is_php()

is_php (*\$version* = '5.3.0')

- **\$version** (*string*) – Version number

bool

Determines if the PHP version being used is greater than the supplied version number.

Example:

```
if (is_php('5.3'))
{
    $str = quoted_printable_encode($str);
}
```

Returns boolean TRUE if the installed version of PHP is equal to or greater than the supplied version number. Returns FALSE if the installed version of PHP is lower than the supplied version number.

is_really_writable()

is_really_writable (*\$file*)

- **\$file** (*string*) – File path

bool

`is_writable()` returns TRUE on Windows servers when you really can't write to the file as the OS reports to PHP as FALSE only if the read-only attribute is marked.

This function determines if a file is actually writable by attempting to write to it first. Generally only recommended on platforms where this information may be unreliable.

Example:

```
if (is_really_writable('file.txt'))
{
    echo "I could write to this if I wanted to";
}
else
{
    echo "File is not writable";
}
```

config_item()

config_item (*\$key*)

- **\$key** (*string*) – Config item key

mixed

The *Config Library* is the preferred way of accessing configuration information, however `config_item()` can be used to retrieve single keys. See *Config Library* documentation for more information.

show_error()

show_error (*\$message*, *\$status_code*, *\$heading* = 'An Error Was Encountered')

- **\$message** (*mixed*) – Error message
- **\$status_code** (*int*) – HTTP Response status code
- **\$heading** (*string*) – Error page heading

void

This function calls `CI_Exception::show_error()`. For more info, please see the *Error Handling* documentation.

show_404()

show_404 (*\$page* = '', *\$log_error* = TRUE)

- **\$page** (*string*) – URI string
- **\$log_error** (*bool*) – Whether to log the error

void

This function calls `CI_Exception::show_404()`. For more info, please see the *Error Handling* documentation.

log_message()

log_message (*\$level*, *\$message*)

- **\$level** (*string*) – Log level: ‘error’, ‘debug’ or ‘info’
- **\$message** (*string*) – Message to log

void

This function is an alias for `CI_Log::write_log()`. For more info, please see the *Error Handling* documentation.

set_status_header()

set_status_header (*\$code*, *\$text* = ‘’)

- **\$code** (*int*) – HTTP Reponse status code
- **\$text** (*string*) – A custom message to set with the status code

void

Permits you to manually set a server status header. Example:

```
set_status_header(401);  
// Sets the header as: Unauthorized
```

See [here](#) for a full list of headers.

remove_invisible_characters()

remove_invisible_characters (*\$str*, *\$url_encoded* = *TRUE*)

- **\$str** (*string*) – Input string
- **\$url_encoded** (*bool*) – Whether to remove URL-encoded characters as well

string

This function prevents inserting NULL characters between ASCII characters, like `Java\0script`.

Example:

```
remove_invisible_characters('Java\0script');  
// Returns: 'Javascript'
```

html_escape()

html_escape (*\$var*)

- **\$var** (*mixed*) – Variable to escape (string or array)

mixed

This function acts as an alias for PHP's native `htmlspecialchars()` function, with the advantage of being able to accept an array of strings.

It is useful in preventing Cross Site Scripting (XSS).

get_mimes()

get_mimes()

array

This function returns a *reference* to the MIMEs array from *application/config/mimes.php*.

is_https()

is_https()

bool

Returns TRUE if a secure (HTTPS) connection is used and FALSE in any other case (including non-HTTP requests).

is_cli()

is_cli()

bool

Returns TRUE if the application is run through the command line and FALSE if not.

: This function checks both if the `PHP_SAPI` value is 'cli' or if the `STDIN` constant is defined.

function_usable()

function_usable (*\$function_name*)

- **\$function_name** (*string*) – Function name

bool

Returns TRUE if a function exists and is usable, FALSE otherwise.

This function runs a `function_exists()` check and if the *Suhosin extension* <<http://www.hardened-php.net/suhosin/>> is loaded, checks if it doesn't disable the function being checked.

It is useful if you want to check for the availability of functions such as `eval()` and `exec()`, which are dangerous and might be disabled on servers with highly restrictive security policies.

10.12.16 URI Routing

Typically there is a one-to-one relationship between a URL string and its corresponding controller class/method. The segments in a URI normally follow this pattern:

```
example.com/class/function/id/
```

In some instances, however, you may want to remap this relationship so that a different class/method can be called instead of the one corresponding to the URL.

For example, let's say you want your URLs to have this prototype:

```
example.com/product/1/  
example.com/product/2/  
example.com/product/3/  
example.com/product/4/
```

Normally the second segment of the URL is reserved for the method name, but in the example above it instead has a product ID. To overcome this, CodeIgniter allows you to remap the URI handler.

Setting your own routing rules

Routing rules are defined in your *application/config/routes.php* file. In it you'll see an array called `$route` that permits you to specify your own routing criteria. Routes can either be specified using wildcards or Regular Expressions.

Wildcards

A typical wildcard route might look something like this:

```
$route['product/:num'] = 'catalog/product_lookup';
```

In a route, the array key contains the URI to be matched, while the array value contains the destination it should be re-routed to. In the above example, if the literal word “product” is found in the first segment of the URL, and a number is found in the second segment, the “catalog” class and the “product_lookup” method are instead used.

You can match literal values or you can use two wildcard types:

(:num) will match a segment containing only numbers. **(:any)** will match a segment containing any character (except for `'`, which is the segment delimiter).

: Wildcards are actually aliases for regular expressions, with **:any** being translated to `[^/]+` and **:num** to `[0-9]+`, respectively.

: Routes will run in the order they are defined. Higher routes will always take precedence over lower ones.

: Route rules are not filters! Setting a rule of e.g. `'foo/bar/(num)'` will not prevent controller *Foo* and method *bar* to be called with a non-numeric value if that is a valid route.

Examples

Here are a few routing examples:

```
$route['journals'] = 'blogs';
```

A URL containing the word “journals” in the first segment will be remapped to the “blogs” class.

```
$route['blog/joe'] = 'blogs/users/34';
```

A URL containing the segments `blog/joe` will be remapped to the “blogs” class and the “users” method. The ID will be set to “34”.

```
$route['product/(:any)'] = 'catalog/product_lookup';
```

A URL with “product” as the first segment, and anything in the second will be remapped to the “catalog” class and the “product_lookup” method.

```
$route['product/(:num)'] = 'catalog/product_lookup_by_id/$1';
```

A URL with “product” as the first segment, and a number in the second will be remapped to the “catalog” class and the “product_lookup_by_id” method passing in the match as a variable to the method.

: Do not use leading/trailing slashes.

Regular Expressions

If you prefer you can use regular expressions to define your routing rules. Any valid regular expression is allowed, as are back-references.

: If you use back-references you must use the dollar syntax rather than the double backslash syntax.

A typical RegEx route might look something like this:

```
$route['products/([a-z]+)/(\d+)'] = '$1/id_$2';
```

In the above example, a URI similar to `products/shirts/123` would instead call the “shirts” controller class and the “id_123” method.

With regular expressions, you can also catch a segment containing a forward slash (/), which would usually represent the delimiter between multiple segments. For example, if a user accesses a password protected area of your web application and you wish to be able to redirect them back to the same page after they log in, you may find this example useful:

```
$route['login/(.)'] = 'auth/login/$1';
```

That will call the “auth” controller class and its `login()` method, passing everything contained in the URI after `login/` as a parameter.

For those of you who don’t know regular expressions and want to learn more about them, *regular-expressions.info* <<http://www.regular-expressions.info/>> might be a good starting point.

: You can also mix and match wildcards with regular expressions.

Callbacks

If you are using PHP >= 5.3 you can use callbacks in place of the normal routing rules to process the back-references. Example:

```
$route['products/([a-zA-Z]+)/edit/(\d+)'] = function ($product_type, $id)
{
    return 'catalog/product_edit/' . strtolower($product_type) . '/' . $id;
};
```

Using HTTP verbs in routes

It is possible to use HTTP verbs (request method) to define your routing rules. This is particularly useful when building RESTful applications. You can use standard HTTP verbs (GET, PUT, POST, DELETE, PATCH) or a custom one such (e.g. PURGE). HTTP verb rules are case-insensitive. All you need to do is to add the verb as an array key to your route. Example:

```
$route['products']['put'] = 'product/insert';
```

In the above example, a PUT request to URI “products” would call the `Product::insert()` controller method.

```
$route['products/(:num)']['DELETE'] = 'product/delete/$1';
```

A DELETE request to URL with “products” as first the segment and a number in the second will be mapped to the `Product::delete()` method, passing the numeric value as the first parameter.

Using HTTP verbs is of course, optional.

Reserved Routes

There are three reserved routes:

```
$route['default_controller'] = 'welcome';
```

This route indicates which controller class should be loaded if the URI contains no data, which will be the case when people load your root URL. In the above example, the “welcome” class would be loaded. You are encouraged to always have a default route otherwise a 404 page will appear by default.

```
$route['404_override'] = '';
```

This route indicates which controller class should be loaded if the requested controller is not found. It will override the default 404 error page. It won't affect to the `show_404()` function, which will continue loading the default *error_404.php* file at *application/views/errors/error_404.php*.

```
$route['translate_uri_dashes'] = FALSE;
```

As evident by the boolean value, this is not exactly a route. This option enables you to automatically replace dashes ('-') with underscores in the controller and method URI segments, thus saving you additional route entries if you need to do that. This is required, because the dash isn't a valid class or method name character and would cause a fatal error if you try to use it.

: The reserved routes must come before any wildcard or regular expression routes.

10.12.17 Error Handling

CodeIgniter lets you build error reporting into your applications using the functions described below. In addition, it has an error logging class that permits error and debugging messages to be saved as text files.

: By default, CodeIgniter displays all PHP errors. You might wish to change this behavior once your development is complete. You'll find the `error_reporting()` function located at the top of your main *index.php* file. Disabling error reporting will NOT prevent log files from being written if there are errors.

Unlike most systems in CodeIgniter, the error functions are simple procedural interfaces that are available globally throughout the application. This approach permits error messages to get triggered without having to worry about class/function scoping.

CodeIgniter also returns a status code whenever a portion of the core calls `exit()`. This exit status code is separate from the HTTP status code, and serves as a notice to other processes that may be watching of whether the script completed successfully, or if not, what kind of problem it encountered that caused it to abort. These values are defined in *application/config/constants.php*. While exit status codes are most useful in CLI settings, returning the proper code helps server software keep track of your scripts and the health of your application.

The following functions let you generate errors:

show_error()

show_error (*\$message*, *\$status_code*, *\$heading* = 'An Error Was Encountered')

- **\$message** (*mixed*) – Error message
- **\$status_code** (*int*) – HTTP Response status code
- **\$heading** (*string*) – Error page heading

void

This function will display the error message supplied to it using the following error template:

`application/views/errors/error_general.php`

The optional parameter `$status_code` determines what HTTP status code should be sent with the error. If `$status_code` is less than 100, the HTTP status code will be set to 500, and the exit status code will be set to `$status_code + EXIT__AUTO_MIN`. If that value is larger than `EXIT__AUTO_MAX`, or if `$status_code` is 100 or higher, the exit status code will be set to `EXIT_ERROR`. You can check in *application/config/constants.php* for more detail.

show_404()

show_404 (*\$page* = '', *\$log_error* = *TRUE*)

- **\$page** (*string*) – URI string
- **\$log_error** (*bool*) – Whether to log the error

void

This function will display the 404 error message supplied to it using the following error template:

`application/views/errors/error_404.php`

The function expects the string passed to it to be the file path to the page that isn't found. The exit status code will be set to `EXIT_UNKNOWN_FILE`. Note that CodeIgniter automatically shows 404 messages if controllers are not found.

CodeIgniter automatically logs any `show_404()` calls. Setting the optional second parameter to `FALSE` will skip logging.

log_message()

log_message (*\$level*, *\$message*, *\$php_error* = *FALSE*)

- **\$level** (*string*) – Log level: 'error', 'debug' or 'info'

- **\$message** (*string*) – Message to log
- **\$php_error** (*bool*) – Whether we’re logging a native PHP error message

void

This function lets you write messages to your log files. You must supply one of three “levels” in the first parameter, indicating what type of message it is (debug, error, info), with the message itself in the second parameter.

Example:

```
if ($some_var == '')
{
    log_message('error', 'Some variable did not contain a value.');
```

}

```
else
{
    log_message('debug', 'Some variable was correctly set');
```

}

```
log_message('info', 'The purpose of some variable is to provide some value.');
```

There are three message types:

1. Error Messages. These are actual errors, such as PHP errors or user errors.
2. Debug Messages. These are messages that assist in debugging. For example, if a class has been initialized, you could log this as debugging info.
3. Informational Messages. These are the lowest priority messages, simply giving information regarding some process. CodeIgniter doesn’t natively generate any info messages but you may want to in your application.

: In order for the log file to actually be written, the *logs* directory must be writable. In addition, you must set the “threshold” for logging in *application/config/config.php*. You might, for example, only want error messages to be logged, and not the other two types. If you set it to zero logging will be disabled.

10.12.18 Web Page Caching

CodeIgniter lets you cache your pages in order to achieve maximum performance.

Although CodeIgniter is quite fast, the amount of dynamic information you display in your pages will correlate directly to the server resources, memory, and processing cycles utilized, which affect your page load speeds. By caching your pages, since they are saved in their fully rendered state, you can achieve performance that nears that of static web pages.

How Does Caching Work?

Caching can be enabled on a per-page basis, and you can set the length of time that a page should remain cached before being refreshed. When a page is loaded for the first time, the cache file will be written to your application/cache folder. On subsequent page loads the cache file will be retrieved and sent to the requesting user’s browser. If it has expired, it will be deleted and refreshed before being sent to the browser.

Enabling Caching

To enable caching, put the following tag in any of your controller methods:

```
$this->output->cache($n);
```

Where `$n` is the number of **minutes** you wish the page to remain cached between refreshes.

The above tag can go anywhere within a method. It is not affected by the order that it appears, so place it wherever it seems most logical to you. Once the tag is in place, your pages will begin being cached.

: Because of the way CodeIgniter stores content for output, caching will only work if you are generating display for your controller with a *view*.

: Before the cache files can be written you must set the file permissions on your *application/cache/* directory such that it is writable.

Deleting Caches

If you no longer wish to cache a file you can remove the caching tag and it will no longer be refreshed when it expires.

: Removing the tag will not delete the cache immediately. It will have to expire normally.

If you need to manually delete the cache, you can use the `delete_cache()` method:

```
// Deletes cache for the currently requested URI
$this->output->delete_cache();
```

```
// Deletes cache for /foo/bar
$this->output->delete_cache('/foo/bar');
```

10.12.19 Profiling Your Application

The Profiler Class will display benchmark results, queries you have run, and `$_POST` data at the bottom of your pages. This information can be useful during development in order to help with debugging and optimization.

Initializing the Class

: This class does NOT need to be initialized. It is loaded automatically by the *Output Library* if profiling is enabled as shown below.

Enabling the Profiler

To enable the profiler place the following line anywhere within your *Controller* methods:

```
$this->output->enable_profiler(TRUE);
```

When enabled a report will be generated and inserted at the bottom of your pages.

To disable the profiler you will use:

```
$this->output->enable_profiler(FALSE);
```

Setting Benchmark Points

In order for the Profiler to compile and display your benchmark data you must name your mark points using specific syntax.

Please read the information on setting Benchmark points in the *Benchmark Library* page.

Enabling and Disabling Profiler Sections

Each section of Profiler data can be enabled or disabled by setting a corresponding config variable to TRUE or FALSE. This can be done one of two ways. First, you can set application wide defaults with the *application/config/profiler.php* config file.

Example:

```
$config['config']          = FALSE;
$config['queries']         = FALSE;
```

In your controllers, you can override the defaults and config file values by calling the `set_profiler_sections()` method of the *Output Library*:

```
$sections = array(
    'config' => TRUE,
    'queries' => TRUE
);

$this->output->set_profiler_sections($sections);
```

Available sections and the array key used to access them are described in the table below.

Key	Description	Default
benchmarks	Elapsed time of Benchmark points and total execution time	TRUE
config	CodeIgniter Config variables	TRUE
controller_info	The Controller class and method requested	TRUE
get	Any GET data passed in the request	TRUE
http_headers	The HTTP headers for the current request	TRUE
memory_usage	Amount of memory consumed by the current request, in bytes	TRUE
post	Any POST data passed in the request	TRUE
queries	Listing of all database queries executed, including execution time	TRUE
uri_string	The URI of the current request	TRUE
session_data	Data stored in the current session	TRUE
query_toggle_count	The number of queries after which the query block will default to hidden.	25

10.12.20 Running via the CLI

As well as calling an applications *Controllers* via the URL in a browser they can also be loaded via the command-line interface (CLI).

Page Contents

- Running via the CLI
 - What is the CLI?
 - Why run via the command-line?
 - Let's try it: Hello World!
 - That's it!

What is the CLI?

The command-line interface is a text-based method of interacting with computers. For more information, check the [Wikipedia article](#).

Why run via the command-line?

There are many reasons for running CodeIgniter from the command-line, but they are not always obvious.

- Run your cron-jobs without needing to use *wget* or *curl*
- Make your cron-jobs inaccessible from being loaded in the URL by checking the return value of `is_cli()`.
- Make interactive “tasks” that can do things like set permissions, prune cache folders, run backups, etc.
- Integrate with other applications in other languages. For example, a random C++ script could call one command and run code in your models!

Let’s try it: Hello World!

Let’s create a simple controller so you can see it in action. Using your text editor, create a file called `Tools.php`, and put the following code in it:

```
<?php
class Tools extends CI_Controller {

    public function message($to = 'World')
    {
        echo "Hello {$to}!".PHP_EOL;
    }
}
```

Then save the file to your *application/controllers/* folder.

Now normally you would visit the your site using a URL similar to this:

```
example.com/index.php/tools/message/to
```

Instead, we are going to open Terminal in Mac/Linux or go to Run > “cmd” in Windows and navigate to our CodeIgniter project.

```
$ cd /path/to/project;
$ php index.php tools message
```

If you did it right, you should see *Hello World!* printed.

```
$ php index.php tools message "John Smith"
```

Here we are passing it a argument in the same way that URL parameters work. “John Smith” is passed as a argument and output is:

```
Hello John Smith!
```

That’s it!

That, in a nutshell, is all there is to know about controllers on the command line. Remember that this is just a normal controller, so routing and `_remap()` works fine.

10.12.21 Managing your Applications

By default it is assumed that you only intend to use CodeIgniter to manage one application, which you will build in your *application/* directory. It is possible, however, to have multiple sets of applications that share a single CodeIgniter installation, or even to rename or relocate your application directory.

Renaming the Application Directory

If you would like to rename your application directory you may do so as long as you open your main `index.php` file and set its name using the `$application_folder` variable:

```
$application_folder = 'application';
```

Relocating your Application Directory

It is possible to move your application directory to a different location on your server than your web root. To do so open your main `index.php` and set a *full server path* in the `$application_folder` variable:

```
$application_folder = '/path/to/your/application';
```

Running Multiple Applications with one CodeIgniter Installation

If you would like to share a common CodeIgniter installation to manage several different applications simply put all of the directories located inside your application directory into their own sub-directory.

For example, let's say you want to create two applications, named “foo” and “bar”. You could structure your application directories like this:

```
applications/foo/  
applications/foo/config/  
applications/foo/controllers/  
applications/foo/errors/  
applications/foo/libraries/  
applications/foo/models/  
applications/foo/views/  
applications/bar/  
applications/bar/config/  
applications/bar/controllers/  
applications/bar/errors/  
applications/bar/libraries/  
applications/bar/models/  
applications/bar/views/
```

To select a particular application for use requires that you open your main `index.php` file and set the `$application_folder` variable. For example, to select the “foo” application for use you would do this:

```
$application_folder = 'applications/foo';
```

: Each of your applications will need its own `index.php` file which calls the desired application. The `index.php` file can be named anything you want.

10.12.22 Handling Multiple Environments

Developers often desire different system behavior depending on whether an application is running in a development or production environment. For example, verbose error output is something that would be useful while developing an application, but it may also pose a security issue when “live”.

The ENVIRONMENT Constant

By default, CodeIgniter comes with the environment constant set to use the value provided in `$_SERVER['CI_ENV']`, otherwise defaults to ‘development’. At the top of `index.php`, you will see:

```
define('ENVIRONMENT', isset($_SERVER['CI_ENV']) ? $_SERVER['CI_ENV'] : 'development');
```

This server variable can be set in your `.htaccess` file, or Apache config using [SetEnv](#). Alternative methods are available for nginx and other servers, or you can remove this logic entirely and set the constant based on the `HTTP_HOST` or IP.

In addition to affecting some basic framework behavior (see the next section), you may use this constant in your own development to differentiate between which environment you are running in.

Effects On Default Framework Behavior

There are some places in the CodeIgniter system where the `ENVIRONMENT` constant is used. This section describes how default framework behavior is affected.

Error Reporting

Setting the `ENVIRONMENT` constant to a value of ‘development’ will cause all PHP errors to be rendered to the browser when they occur. Conversely, setting the constant to ‘production’ will disable all error output. Disabling error reporting in production is a *good security practice*.

Configuration Files

Optionally, you can have CodeIgniter load environment-specific configuration files. This may be useful for managing things like differing API keys across multiple environments. This is described in more detail in the environment section of the Config Class documentation.

10.12.23 Alternate PHP Syntax for View Files

If you do not utilize CodeIgniter’s *template engine*, you’ll be using pure PHP in your View files. To minimize the PHP code in these files, and to make it easier to identify the code blocks it is recommended that you use PHP’s alternative syntax for control structures and short tag echo statements. If you are not familiar with this syntax, it allows you to eliminate the braces from your code, and eliminate “echo” statements.

Automatic Short Tag Support

: If you find that the syntax described in this page does not work on your server it might be that “short tags” are disabled in your PHP ini file. CodeIgniter will optionally rewrite short tags on-the-fly, allowing you to use that syntax even if your server doesn’t support it. This feature can be enabled in your `config/config.php` file.

Please note that if you do use this feature, if PHP errors are encountered in your **view files**, the error message and line number will not be accurately shown. Instead, all errors will be shown as `eval()` errors.

Alternative Echos

Normally to echo, or print out a variable you would do this:

```
<?php echo $variable; ?>
```

With the alternative syntax you can instead do it this way:

```
<?=$variable?>
```

Alternative Control Structures

Controls structures, like if, for, foreach, and while can be written in a simplified format as well. Here is an example using foreach:

```
<ul>

<?php foreach ($todo as $item): ?>

    <li><?=$item?></li>

<?php endforeach; ?>

</ul>
```

Notice that there are no braces. Instead, the end brace is replaced with `endforeach`. Each of the control structures listed above has a similar closing syntax: `endif`, `endfor`, `endforeach`, and `endwhile`

Also notice that instead of using a semicolon after each structure (except the last one), there is a colon. This is important!

Here is another example, using `if/elseif/else`. Notice the colons:

```
<?php if ($username === 'sally'): ?>

    <h3>Hi Sally</h3>

<?php elseif ($username === 'joe'): ?>

    <h3>Hi Joe</h3>

<?php else: ?>

    <h3>Hi unknown user</h3>

<?php endif; ?>
```

10.12.24 Security

This page describes some “best practices” regarding web security, and details CodeIgniter’s internal security features.

URI Security

CodeIgniter is fairly restrictive regarding which characters it allows in your URI strings in order to help minimize the possibility that malicious data can be passed to your application. URIs may only contain the following:

- Alpha-numeric text (latin characters only)
- Tilde: ~
- Percent sign: %
- Period: .
- Colon: :
- Underscore: _
- Dash: -
- Space

Register_globals

During system initialization all global variables are unset, except those found in the `$_GET`, `$_POST`, and `$_COOKIE` arrays. The unsetting routine is effectively the same as `register_globals = off`.

display_errors

In production environments, it is typically desirable to “disable” PHP’s error reporting by setting the internal `display_errors` flag to a value of 0. This disables native PHP errors from being rendered as output, which may potentially contain sensitive information.

Setting CodeIgniter’s **ENVIRONMENT** constant in `index.php` to a value of ‘**production**’ will turn off these errors. In development mode, it is recommended that a value of ‘development’ is used. More information about differentiating between environments can be found on the *Handling Environments* page.

magic_quotes_runtime

The `magic_quotes_runtime` directive is turned off during system initialization so that you don’t have to remove slashes when retrieving data from your database.

Best Practices

Before accepting any data into your application, whether it be POST data from a form submission, COOKIE data, URI data, XML-RPC data, or even data from the SERVER array, you are encouraged to practice this three step approach:

1. Filter the data as if it were tainted.
2. Validate the data to ensure it conforms to the correct type, length, size, etc. (sometimes this step can replace step one)
3. Escape the data before submitting it into your database.

CodeIgniter provides the following functions to assist in this process:

XSS Filtering

CodeIgniter comes with a Cross Site Scripting filter. This filter looks for commonly used techniques to embed malicious JavaScript into your data, or other types of code that attempt to hijack cookies or do other malicious things. The XSS Filter is described *here*.

Validate the data

CodeIgniter has a *Form Validation Library* that assists you in validating, filtering, and prepping your data.

Escape all data before database insertion

Never insert information into your database without escaping it. Please see the section that discusses *database queries* for more information.

Hide your files

Another good security practice is to only leave your *index.php* and “assets” (e.g. .js, css and image files) under your server’s *webroot* directory (most commonly named “htdocs/”). These are the only files that you would need to be accessible from the web.

Allowing your visitors to see anything else would potentially allow them to access sensitive data, execute scripts, etc.

If you’re not allowed to do that, you can try using a .htaccess file to restrict access to those resources.

CodeIgniter will have an index.html file in all of its directories in an attempt to hide some of this data, but have it in mind that this is not enough to prevent a serious attacker.

10.12.25 PHP Style Guide

The following page describes the coding styles adhered to when contributing to the development of CodeIgniter. There is no requirement to use these styles in your own CodeIgniter application, though they are recommended.

Table of Contents

- PHP Style Guide
 - File Format
 - * TextMate
 - * BBEdit
 - PHP Closing Tag
 - File Naming
 - Class and Method Naming
 - Variable Names
 - Commenting
 - Constants
 - TRUE, FALSE, and NULL
 - Logical Operators
 - Comparing Return Values and Typecasting
 - Debugging Code
 - Whitespace in Files
 - Compatibility
 - One File per Class
 - Whitespace
 - Line Breaks
 - Code Indenting
 - Bracket and Parenthetic Spacing
 - Localized Text
 - Private Methods and Variables
 - PHP Errors
 - Short Open Tags
 - One Statement Per Line
 - Strings
 - SQL Queries
 - Default Function Arguments

File Format

Files should be saved with Unicode (UTF-8) encoding. The BOM should *not* be used. Unlike UTF-16 and UTF-32, there's no byte order to indicate in a UTF-8 encoded file, and the BOM can have a negative side effect in PHP of sending output, preventing the application from being able to set its own headers. Unix line endings should be used (LF).

Here is how to apply these settings in some of the more common text editors. Instructions for your text editor may vary; check your text editor's documentation.

TextMate

1. Open the Application Preferences
2. Click Advanced, and then the "Saving" tab
3. In "File Encoding", select "UTF-8 (recommended)"
4. In "Line Endings", select "LF (recommended)"
5. *Optional:* Check "Use for existing files as well" if you wish to modify the line endings of files you open to your new preference.

BEdit

1. Open the Application Preferences
2. Select “Text Encodings” on the left.
3. In “Default text encoding for new documents”, select “Unicode (UTF-8, no BOM)”
4. *Optional:* In “If file’s encoding can’t be guessed, use”, select “Unicode (UTF-8, no BOM)”
5. Select “Text Files” on the left.
6. In “Default line breaks”, select “Mac OS X and Unix (LF)”

PHP Closing Tag

The PHP closing tag on a PHP document `?>` is optional to the PHP parser. However, if used, any whitespace following the closing tag, whether introduced by the developer, user, or an FTP application, can cause unwanted output, PHP errors, or if the latter are suppressed, blank pages. For this reason, all PHP files should **OMIT** the closing PHP tag, and instead use a comment block to mark the end of file and its location relative to the application root. This allows you to still identify a file as being complete and not truncated.

INCORRECT:

```
<?php

echo "Here's my code!";

?>
```

CORRECT:

```
<?php

echo "Here's my code!";

/* End of file Myfile.php */
/* Location: ./system/modules/mymodule/myfile.php */
```

: There should be no empty line or newline character(s) following the closing comments. If you happen to see one when submitting a pull request, please check your IDE settings and fix it.

File Naming

Class files must be named in a Ucfirst-like manner, while any other file name (configurations, views, generic scripts, etc.) should be in all lowercase.

INCORRECT:

```
somelibrary.php
someLibrary.php
SOMELIBRARY.php
Some_Library.php

Application_config.php
Application_Config.php
applicationConfig.php
```

CORRECT:

```
Somelibrary.php
Some_library.php
```

```
applicationconfig.php
application_config.php
```

Furthermore, class file names should match the name of the class itself. For example, if you have a class named *Myclass*, then its filename must be **Myclass.php**.

Class and Method Naming

Class names should always start with an uppercase letter. Multiple words should be separated with an underscore, and not CamelCased.

INCORRECT:

```
class superclass
class SuperClass
```

CORRECT:

```
class Super_class

class Super_class {

    public function __construct()
    {

    }

}
```

Class methods should be entirely lowercased and named to clearly indicate their function, preferably including a verb. Try to avoid overly long and verbose names. Multiple words should be separated with an underscore.

INCORRECT:

```
function fileproperties()           // not descriptive and needs underscore separator
function fileProperties()           // not descriptive and uses CamelCase
function getfileproperties()        // Better! But still missing underscore separator
function getFileProperties()         // uses CamelCase
function get_the_file_properties_from_the_file() // wordy
```

CORRECT:

```
function get_file_properties() // descriptive, underscore separator, and all lowercase letters
```

Variable Names

The guidelines for variable naming are very similar to those used for class methods. Variables should contain only lowercase letters, use underscore separators, and be reasonably named to indicate their purpose and contents. Very short, non-word variables should only be used as iterators in `for()` loops.

INCORRECT:

```
$j = 'foo';           // single letter variables should only be used in for() loops
$str                 // contains uppercase letters
$bufferedText       // uses CamelCasing, and could be shortened without losing semantic meaning
$groupid             // multiple words, needs underscore separator
$name_of_last_city_used // too long
```

CORRECT:

```
for ($j = 0; $j < 10; $j++)
$str
$buffer
$group_id
$last_city
```

Commenting

In general, code should be commented prolifically. It not only helps describe the flow and intent of the code for less experienced programmers, but can prove invaluable when returning to your own code months down the line. There is not a required format for comments, but the following are recommended.

DocBlock style comments preceding class, method, and property declarations so they can be picked up by IDEs:

```
/**
 * Super Class
 *
 * @package      Package Name
 * @subpackage   Subpackage
 * @category     Category
 * @author       Author Name
 * @link         http://example.com
 */
class Super_class {

/**
 * Encodes string for use in XML
 *
 * @param        string  $str    Input string
 * @return       string
 */
function xml_encode($str)

/**
 * Data for class manipulation
 *
 * @var array
 */
public $data = array();
```

Use single line comments within code, leaving a blank line between large comment blocks and code.

```
// break up the string by newlines
$parts = explode("\n", $str);

// A longer comment that needs to give greater detail on what is
// occurring and why can use multiple single-line comments. Try to
// keep the width reasonable, around 70 characters is the easiest to
// read. Don't hesitate to link to permanent external resources
// that may provide greater detail:
```

```
//
// http://example.com/information_about_something/in_particular/

$parts = $this->foo($parts);
```

Constants

Constants follow the same guidelines as do variables, except constants should always be fully uppercase. *Always use CodeIgniter constants when appropriate, i.e. SLASH, LD, RD, PATH_CACHE, etc.*

INCORRECT:

```
myConstant      // missing underscore separator and not fully uppercase
N               // no single-letter constants
S_C_VER         // not descriptive
$str = str_replace('{foo}', 'bar', $str);           // should use LD and RD constants
```

CORRECT:

```
MY_CONSTANT
NEWLINE
SUPER_CLASS_VERSION
$str = str_replace(LD.'foo'.RD, 'bar', $str);
```

TRUE, FALSE, and NULL

TRUE, FALSE, and NULL keywords should always be fully uppercase.

INCORRECT:

```
if ($foo == true)
    $bar = false;
function foo($bar = null)
```

CORRECT:

```
if ($foo == TRUE)
    $bar = FALSE;
function foo($bar = NULL)
```

Logical Operators

Use of the || “or” comparison operator is discouraged, as its clarity on some output devices is low (looking like the number 11, for instance). && is preferred over AND but either are acceptable, and a space should always precede and follow !.

INCORRECT:

```
if ($foo || $bar)
if ($foo AND $bar) // okay but not recommended for common syntax highlighting applications
if (!$foo)
if (! is_array($foo))
```

CORRECT:

```
if ($foo OR $bar)
if ($foo && $bar) // recommended
if ( ! $foo)
if ( ! is_array($foo))
```

Comparing Return Values and Typecasting

Some PHP functions return FALSE on failure, but may also have a valid return value of "" or 0, which would evaluate to FALSE in loose comparisons. Be explicit by comparing the variable type when using these return values in conditionals to ensure the return value is indeed what you expect, and not a value that has an equivalent loose-type evaluation.

Use the same stringency in returning and checking your own variables. Use === and !== as necessary.

INCORRECT:

```
// If 'foo' is at the beginning of the string, strpos will return a 0,
// resulting in this conditional evaluating as TRUE
if (strpos($str, 'foo') == FALSE)
```

CORRECT:

```
if (strpos($str, 'foo') === FALSE)
```

INCORRECT:

```
function build_string($str = "")
{
    if ($str == "") // uh-oh!  What if FALSE or the integer 0 is passed as an argument?
    {

    }
}
```

CORRECT:

```
function build_string($str = "")
{
    if ($str === "")
    {

    }
}
```

See also information regarding [typecasting](#), which can be quite useful. Typecasting has a slightly different effect which may be desirable. When casting a variable as a string, for instance, NULL and boolean FALSE variables become empty strings, 0 (and other numbers) become strings of digits, and boolean TRUE becomes "1":

```
$str = (string) $str; // cast $str as a string
```

Debugging Code

Do not leave debugging code in your submissions, even when commented out. Things such as `var_dump()`, `print_r()`, `die()/exit()` should not be included in your code unless it serves a specific purpose other than debugging.

Whitespace in Files

No whitespace can precede the opening PHP tag or follow the closing PHP tag. Output is buffered, so whitespace in your files can cause output to begin before CodeIgniter outputs its content, leading to errors and an inability for CodeIgniter to send proper headers.

Compatibility

CodeIgniter requires a minimum PHP version of 5.2.4. Your code must either be compatible with this minimum requirement, provide a suitable fallback, or be an optional feature that dies quietly without affecting a user's application.

Additionally, do not use PHP functions that require non-default libraries to be installed unless your code contains an alternative method when the function is not available.

One File per Class

Use separate files for each class, unless the classes are *closely related*. An example of a CodeIgniter file that contains multiple classes is the Xmlrpc library file.

Whitespace

Use tabs for whitespace in your code, not spaces. This may seem like a small thing, but using tabs instead of whitespace allows the developer looking at your code to have indentation at levels that they prefer and customize in whatever application they use. And as a side benefit, it results in (slightly) more compact files, storing one tab character versus, say, four space characters.

Line Breaks

Files must be saved with Unix line breaks. This is more of an issue for developers who work in Windows, but in any case ensure that your text editor is setup to save files with Unix line breaks.

Code Indenting

Use Allman style indenting. With the exception of Class declarations, braces are always placed on a line by themselves, and indented at the same level as the control statement that “owns” them.

INCORRECT:

```
function foo($bar) {
    // ...
}

foreach ($arr as $key => $val) {
    // ...
}

if ($foo == $bar) {
    // ...
} else {
    // ...
}

for ($i = 0; $i < 10; $i++)
```

```
        {
            for ($j = 0; $j < 10; $j++)
            {
                // ...
            }
        }

try {
    // ...
}
catch() {
    // ...
}
```

CORRECT:

```
function foo($bar)
{
    // ...
}

foreach ($arr as $key => $val)
{
    // ...
}

if ($foo == $bar)
{
    // ...
}
else
{
    // ...
}

for ($i = 0; $i < 10; $i++)
{
    for ($j = 0; $j < 10; $j++)
    {
        // ...
    }
}

try
{
    // ...
}
catch()
{
    // ...
}
```

Bracket and Parenthetic Spacing

In general, parenthesis and brackets should not use any additional spaces. The exception is that a space should always follow PHP control structures that accept arguments with parenthesis (declare, do-while, elseif, for, foreach, if, switch, while), to help distinguish them from functions and increase readability.

INCORRECT:

```
$arr[ $foo ] = 'foo';
```

CORRECT:

```
$arr[$foo] = 'foo'; // no spaces around array keys
```

INCORRECT:

```
function foo ( $bar )
{

}
```

CORRECT:

```
function foo($bar) // no spaces around parenthesis in function declarations
{

}
```

INCORRECT:

```
foreach( $query->result() as $row )
```

CORRECT:

```
foreach ( $query->result() as $row) // single space following PHP control structures, but not in inter
```

Localized Text

CodeIgniter libraries should take advantage of corresponding language files whenever possible.

INCORRECT:

```
return "Invalid Selection";
```

CORRECT:

```
return $this->lang->line('invalid_selection');
```

Private Methods and Variables

Methods and variables that are only accessed internally, such as utility and helper functions that your public methods use for code abstraction, should be prefixed with an underscore.

```
public function convert_text()
private function _convert_text()
```

PHP Errors

Code must run error free and not rely on warnings and notices to be hidden to meet this requirement. For instance, never access a variable that you did not set yourself (such as `$_POST` array keys) without first checking to see that it `isset()`.

Make sure that your dev environment has error reporting enabled for ALL users, and that `display_errors` is enabled in the PHP environment. You can check this setting with:

```
if (ini_get('display_errors') == 1)
{
    exit "Enabled";
}
```

On some servers where *display_errors* is disabled, and you do not have the ability to change this in the `php.ini`, you can often enable it with:

```
ini_set('display_errors', 1);
```

: Setting the `display_errors` setting with `ini_set()` at runtime is not identical to having it enabled in the PHP environment. Namely, it will not have any effect if the script has fatal errors.

Short Open Tags

Always use full PHP opening tags, in case a server does not have *short_open_tag* enabled.

INCORRECT:

```
<? echo $foo; ?>

<?=$foo?>
```

CORRECT:

```
<?php echo $foo; ?>
```

: PHP 5.4 will always have the `<?=>` tag available.

One Statement Per Line

Never combine statements on one line.

INCORRECT:

```
$foo = 'this'; $bar = 'that'; $bat = str_replace($foo, $bar, $bag);
```

CORRECT:

```
$foo = 'this';
$bar = 'that';
$bat = str_replace($foo, $bar, $bag);
```

Strings

Always use single quoted strings unless you need variables parsed, and in cases where you do need variables parsed, use braces to prevent greedy token parsing. You may also use double-quoted strings if the string contains single quotes, so you do not have to use escape characters.

INCORRECT:

```
"My String"                // no variable parsing, so no use for double quotes
"My string $foo"            // needs braces
'SELECT foo FROM bar WHERE baz = \'bag\'' // ugly
```

CORRECT:

```
'My String'
"My string {$foo}"
"SELECT foo FROM bar WHERE baz = 'bag'"
```

SQL Queries

SQL keywords are always capitalized: SELECT, INSERT, UPDATE, WHERE, AS, JOIN, ON, IN, etc.

Break up long queries into multiple lines for legibility, preferably breaking for each clause.

INCORRECT:

```
// keywords are lowercase and query is too long for
// a single line (... indicates continuation of line)
$query = $this->db->query("select foo, bar, baz, foofoo, foobar as raboof, foobaz from exp_pre_email_
...where foo != 'oof' and baz != 'zab' order by foobaz limit 5, 100");
```

CORRECT:

```
$query = $this->db->query("SELECT foo, bar, baz, foofoo, foobar AS raboof, foobaz
                        FROM exp_pre_email_addresses
                        WHERE foo != 'oof'
                        AND baz != 'zab'
                        ORDER BY foobaz
                        LIMIT 5, 100");
```

Default Function Arguments

Whenever appropriate, provide function argument defaults, which helps prevent PHP errors with mistaken calls and provides common fallback values which can save a few lines of code. Example:

```
function foo($bar = '', $baz = FALSE)
```

10.13 Libraries

10.13.1 Benchmarking Class

CodeIgniter has a Benchmarking class that is always active, enabling the time difference between any two marked points to be calculated.

: This class is initialized automatically by the system so there is no need to do it manually.

In addition, the benchmark is always started the moment the framework is invoked, and ended by the output class right before sending the final view to the browser, enabling a very accurate timing of the entire system execution to be shown.

Table of Contents

- Benchmarking Class
 - Using the Benchmark Class
 - Profiling Your Benchmark Points
 - Displaying Total Execution Time
 - Displaying Memory Consumption

Using the Benchmark Class

The Benchmark class can be used within your *controllers*, *views*, or your *models*. The process for usage is this:

1. Mark a start point
2. Mark an end point
3. Run the “elapsed time” function to view the results

Here’s an example using real code:

```
$this->benchmark->mark('code_start');

// Some code happens here

$this->benchmark->mark('code_end');

echo $this->benchmark->elapsed_time('code_start', 'code_end');
```

: The words “code_start” and “code_end” are arbitrary. They are simply words used to set two markers. You can use any words you want, and you can set multiple sets of markers. Consider this example:

```
$this->benchmark->mark('dog');

// Some code happens here

$this->benchmark->mark('cat');

// More code happens here

$this->benchmark->mark('bird');

echo $this->benchmark->elapsed_time('dog', 'cat');
echo $this->benchmark->elapsed_time('cat', 'bird');
echo $this->benchmark->elapsed_time('dog', 'bird');
```

Profiling Your Benchmark Points

If you want your benchmark data to be available to the *Profiler* all of your marked points must be set up in pairs, and each mark point name must end with `_start` and `_end`. Each pair of points must otherwise be named identically. Example:

```
$this->benchmark->mark('my_mark_start');

// Some code happens here...
```

```
$this->benchmark->mark('my_mark_end');

$this->benchmark->mark('another_mark_start');

// Some more code happens here...

$this->benchmark->mark('another_mark_end');
```

Please read the *Profiler page* for more information.

Displaying Total Execution Time

If you would like to display the total elapsed time from the moment CodeIgniter starts to the moment the final output is sent to the browser, simply place this in one of your view templates:

```
<?php echo $this->benchmark->elapsed_time();?>
```

You'll notice that it's the same function used in the examples above to calculate the time between two point, except you are **not** using any parameters. When the parameters are absent, CodeIgniter does not stop the benchmark until right before the final output is sent to the browser. It doesn't matter where you use the function call, the timer will continue to run until the very end.

An alternate way to show your elapsed time in your view files is to use this pseudo-variable, if you prefer not to use the pure PHP:

```
{elapsed_time}
```

: If you want to benchmark anything within your controller functions you must set your own start/end points.

Displaying Memory Consumption

If your PHP installation is configured with `--enable-memory-limit`, you can display the amount of memory consumed by the entire system using the following code in one of your view file:

```
<?php echo $this->benchmark->memory_usage();?>
```

: This function can only be used in your view files. The consumption will reflect the total memory used by the entire app.

An alternate way to show your memory usage in your view files is to use this pseudo-variable, if you prefer not to use the pure PHP:

```
{memory_usage}
```

10.13.2 Caching Driver

CodeIgniter features wrappers around some of the most popular forms of fast and dynamic caching. All but file-based caching require specific server requirements, and a Fatal Exception will be thrown if server requirements are not met.

Table of Contents

- Caching Driver
 - Example Usage
 - Function Reference
 - * is_supported()
 - * get()
 - * save()
 - * delete()
 - * clean()
 - * cache_info()
 - * get_metadata()
 - Drivers
 - * Alternative PHP Cache (APC) Caching
 - * File-based Caching
 - * Memcached Caching
 - * WinCache Caching
 - * Redis Caching
 - * Dummy Cache

Example Usage

The following example will load the cache driver, specify APC as the driver to use, and fall back to file-based caching if APC is not available in the hosting environment.

```
$this->load->driver('cache', array('adapter' => 'apc', 'backup' => 'file'));

if ( ! $foo = $this->cache->get('foo'))
{
    echo 'Saving to the cache!<br />';
    $foo = 'foobarbaz!';

    // Save into the cache for 5 minutes
    $this->cache->save('foo', $foo, 300);
}

echo $foo;
```

You can also prefix cache item names via the **key_prefix** setting, which is useful to avoid collisions when you're running multiple applications on the same environment.

```
$this->load->driver('cache',
    array('adapter' => 'apc', 'backup' => 'file', 'key_prefix' => 'my_')
);

$this->cache->get('foo'); // Will get the cache entry named 'my_foo'
```

Function Reference

class CI_Cache

is_supported()

`CI_Cache::is_supported($driver)`

This function is automatically called when accessing drivers via `$this->cache->get()`. However, if the individual drivers are used, make sure to call this function to ensure the driver is supported in the hosting environment.

- **\$driver** (*string*) – the name of the caching driver

TRUE if supported, FALSE if not

Boolean

```
if ($this->cache->apc->is_supported())
{
    if ($data = $this->cache->apc->get('my_cache'))
    {
        // do things.
    }
}
```

get()

`CI_Cache::get($id)`

This function will attempt to fetch an item from the cache store. If the item does not exist, the function will return FALSE.

- **\$id** (*string*) – name of cached item

The item if it exists, FALSE if it does not

Mixed

```
$foo = $this->cache->get('my_cached_item');
```

save()

`CI_Cache::save($id, $data[, $ttl])`

This function will save an item to the cache store. If saving fails, the function will return FALSE.

- **\$id** (*string*) – name of the cached item
- **\$data** (*mixed*) – the data to save
- **\$ttl** (*int*) – Time To Live, in seconds (default 60)

TRUE on success, FALSE on failure

Boolean

```
$this->cache->save('cache_item_id', 'data_to_cache');
```

delete()

CI_Cache::delete (\$id)

This function will delete a specific item from the cache store. If item deletion fails, the function will return FALSE.

- **\$id** (*string*) – name of cached item

TRUE if deleted, FALSE if the deletion fails

Boolean

```
$this->cache->delete('cache_item_id');
```

clean()

CI_Cache::clean()

This function will 'clean' the entire cache. If the deletion of the cache files fails, the function will return FALSE.

TRUE if deleted, FALSE if the deletion fails

Boolean

```
$this->cache->clean();
```

cache_info()

CI_Cache::cache_info()

This function will return information on the entire cache.

information on the entire cache

Mixed

```
var_dump($this->cache->cache_info());
```

: The information returned and the structure of the data is dependent on which adapter is being used.

get_metadata()

CI_Cache::get_metadata (\$id)

This function will return detailed information on a specific item in the cache.

- **\$id** (*string*) – name of cached item

metadadta for the cached item

Mixed

```
var_dump($this->cache->get_metadata('my_cached_item'));
```

: The information returned and the structure of the data is dependent on which adapter is being used.

Drivers

Alternative PHP Cache (APC) Caching

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->apc->save('foo', 'bar', 10);
```

For more information on APC, please see <http://php.net/apc>.

File-based Caching

Unlike caching from the Output Class, the driver file-based caching allows for pieces of view files to be cached. Use this with care, and make sure to benchmark your application, as a point can come where disk I/O will negate positive gains by caching.

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->file->save('foo', 'bar', 10);
```

Memcached Caching

Multiple Memcached servers can be specified in the memcached.php configuration file, located in the `_application/config/*` directory.

All of the methods listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->memcached->save('foo', 'bar', 10);
```

For more information on Memcached, please see <http://php.net/memcached>.

WinCache Caching

Under Windows, you can also utilize the WinCache driver.

All of the functions listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');  
$this->cache->wincache->save('foo', 'bar', 10);
```

For more information on WinCache, please see <http://php.net/wincache>.

Redis Caching

Redis is an in-memory key-value store which can operate in LRU cache mode. To use it, you need Redis server and phpredis PHP extension <https://github.com/nicolasff/phpredis>.

Config options to connect to redis server must be stored in the application/config/redis.php file. Available options are:

```
$config['socket_type'] = 'tcp'; // 'tcp' or 'unix'
$config['socket'] = '/var/run/redis.sock'; // in case of 'unix' socket type
$config['host'] = '127.0.0.1';
$config['password'] = NULL;
$config['port'] = 6379;
$config['timeout'] = 0;
```

All of the methods listed above can be accessed without passing a specific adapter to the driver loader as follows:

```
$this->load->driver('cache');
$this->cache->redis->save('foo', 'bar', 10);
```

For more information on Redis, please see <http://redis.io>.

Dummy Cache

This is a caching backend that will always ‘miss.’ It stores no data, but lets you keep your caching code in place in environments that don’t support your chosen cache.

10.13.3 Calendaring Class

The Calendar class enables you to dynamically create calendars. Your calendars can be formatted through the use of a calendar template, allowing 100% control over every aspect of its design. In addition, you can pass data to your calendar cells.

Initializing the Class

Like most other classes in CodeIgniter, the Calendar class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('calendar');
```

Once loaded, the Calendar object will be available using:

```
$this->calendar
```

Displaying a Calendar

Here is a very simple example showing how you can display a calendar:

```
$this->load->library('calendar');
echo $this->calendar->generate();
```

The above code will generate a calendar for the current month/year based on your server time. To show a calendar for a specific month and year you will pass this information to the calendar generating function:

```
$this->load->library('calendar');  
echo $this->calendar->generate(2006, 6);
```

The above code will generate a calendar showing the month of June in 2006. The first parameter specifies the year, the second parameter specifies the month.

Passing Data to your Calendar Cells

To add data to your calendar cells involves creating an associative array in which the keys correspond to the days you wish to populate and the array value contains the data. The array is passed to the third parameter of the calendar generating function. Consider this example:

```
$this->load->library('calendar');  
  
$data = array(  
    3 => 'http://example.com/news/article/2006/03/',  
    7 => 'http://example.com/news/article/2006/07/',  
    13 => 'http://example.com/news/article/2006/13/',  
    26 => 'http://example.com/news/article/2006/26/'  
);  
  
echo $this->calendar->generate(2006, 6, $data);
```

Using the above example, day numbers 3, 7, 13, and 26 will become links pointing to the URLs you've provided.

: By default it is assumed that your array will contain links. In the section that explains the calendar template below you'll see how you can customize how data passed to your cells is handled so you can pass different types of information.

Setting Display Preferences

There are seven preferences you can set to control various aspects of the calendar. Preferences are set by passing an array of preferences in the second parameter of the loading function. Here is an example:

```
$prefs = array (  
    'start_day'      => 'saturday',  
    'month_type'     => 'long',  
    'day_type'       => 'short'  
);  
  
$this->load->library('calendar', $prefs);  
  
echo $this->calendar->generate();
```

The above code would start the calendar on saturday, use the “long” month heading, and the “short” day names. More information regarding preferences below.

Preference	Default	Options	Description
template	None	None	A string containing your calendar template. See the template section below.
local_time	time()	None	A Unix timestamp corresponding to the current time.
start_day	sunday	Any week day (sunday, monday, tuesday, etc.)	Sets the day of the week the calendar should start on.
month_type	long	long, short	Determines what version of the month name to use in the header. long = January, short = Jan.
day_type	abr	long, short, abr	Determines what version of the weekday names to use in the column headers. long = Sunday, short = Sun, abr = Su.
show_next_prev	FALSE	TRUE/FALSE (boolean)	Determines whether to display links allowing you to toggle to next/previous months. See information on this feature below.
next_prev_url	none	A URL	Sets the basepath used in the next/previous calendar links.

Showing Next/Previous Month Links

To allow your calendar to dynamically increment/decrement via the next/previous links requires that you set up your calendar code similar to this example:

```
$prefs = array (
    'show_next_prev' => TRUE,
    'next_prev_url'  => 'http://example.com/index.php/calendar/show/'
);

$this->load->library('calendar', $prefs);

echo $this->calendar->generate($this->uri->segment(3), $this->uri->segment(4));
```

You'll notice a few things about the above example:

- You must set the “show_next_prev” to TRUE.
- You must supply the URL to the controller containing your calendar in the “next_prev_url” preference.
- You must supply the “year” and “month” to the calendar generating function via the URI segments where they appear (Note: The calendar class automatically adds the year/month to the base URL you provide.).

Creating a Calendar Template

By creating a calendar template you have 100% control over the design of your calendar. Each component of your calendar will be placed within a pair of pseudo-variables as shown here:

```
$prefs['template'] = '

{table_open}<table border="0" cellpadding="0" cellspacing="0">{/table_open}

{heading_row_start}<tr>{/heading_row_start}

{heading_previous_cell}<th><a href="{previous_url}">&lt;&lt;</a></th>{/heading_previous_cell}
{heading_title_cell}<th colspan="{colspan}">{heading}</th>{/heading_title_cell}
{heading_next_cell}<th><a href="{next_url}">&gt;&gt;</a></th>{/heading_next_cell}

{heading_row_end}</tr>{/heading_row_end}
```

```

{week_row_start}<tr>{/week_row_start}
{week_day_cell}<td>{week_day}</td>{/week_day_cell}
{week_row_end}</tr>{/week_row_end}

{cal_row_start}<tr>{/cal_row_start}

';

$this->load->library('calendar', $prefs);

echo $this->calendar->generate();

```

10.13.4 Shopping Cart Class

The Cart Class permits items to be added to a session that stays active while a user is browsing your site. These items can be retrieved and displayed in a standard “shopping cart” format, allowing the user to update the quantity or remove items from the cart.

Please note that the Cart Class ONLY provides the core “cart” functionality. It does not provide shipping, credit card authorization, or other processing components.

Page Contents

 - * \$this->cart->insert();
 - * \$this->cart->update();
 - * \$this->cart->remove(rowid);
 - * \$this->cart->total();
 - * \$this->cart->total_items();
 - * \$this->cart->contents(boolean);
 - * \$this->cart->get_item(\$row_id);
 - * \$this->cart->has_options(\$row_id);
 - * \$this->cart->product_options(\$row_id);
 - * \$this->cart->destroy();

Initializing the Shopping Cart Class

: The Cart class utilizes CodeIgniter's *Session Class* to save the cart information to a database, so before using the Cart class you must set up a database table as indicated in the *Session Documentation*, and set the session preferences in your application/config/config.php file to utilize a database.

To initialize the Shopping Cart Class in your controller constructor, use the `$this->load->library` function:

```
$this->load->library('cart');
```

Once loaded, the Cart object will be available using:

```
$this->cart
```

: The Cart Class will load and initialize the Session Class automatically, so unless you are using sessions elsewhere in your application, you do not need to load the Session class.

Adding an Item to The Cart

To add an item to the shopping cart, simply pass an array with the product information to the `$this->cart->insert()` function, as shown below:

```
$data = array(
    'id'      => 'sku_123ABC',
    'qty'     => 1,
    'price'   => 39.95,
    'name'    => 'T-Shirt',
    'options' => array('Size' => 'L', 'Color' => 'Red')
);

$this->cart->insert($data);
```

: The first four array indexes above (id, qty, price, and name) are **required**. If you omit any of them the data will not be saved to the cart. The fifth index (options) is optional. It is intended to be used in cases where your product has options associated with it. Use an array for options, as shown above.

The five reserved indexes are:

- **id** - Each product in your store must have a unique identifier. Typically this will be an “sku” or other such identifier.
- **qty** - The quantity being purchased.
- **price** - The price of the item.
- **name** - The name of the item.
- **options** - Any additional attributes that are needed to identify the product. These must be passed via an array.

In addition to the five indexes above, there are two reserved words: rowid and subtotal. These are used internally by the Cart class, so please do NOT use those words as index names when inserting data into the cart.

Your array may contain additional data. Anything you include in your array will be stored in the session. However, it is best to standardize your data among all your products in order to make displaying the information in a table easier.

The insert() method will return the \$rowid if you successfully insert a single item.

Adding Multiple Items to The Cart

By using a multi-dimensional array, as shown below, it is possible to add multiple products to the cart in one action. This is useful in cases where you wish to allow people to select from among several items on the same page.

```
$data = array(
    array(
        'id'      => 'sku_123ABC',
        'qty'     => 1,
        'price'   => 39.95,
        'name'    => 'T-Shirt',
        'options' => array('Size' => 'L', 'Color' => 'Red')
    ),
    array(
        'id'      => 'sku_567ZYX',
        'qty'     => 1,
        'price'   => 9.95,
        'name'    => 'Coffee Mug'
    ),
    array(
        'id'      => 'sku_965QRS',
        'qty'     => 1,
        'price'   => 29.95,
        'name'    => 'Shot Glass'
    )
);

$this->cart->insert($data);
```

Displaying the Cart

To display the cart you will create a *view file* with code similar to the one shown below.

Please note that this example uses the *form helper*.

```
<?php echo form_open('path/to/controller/update/function'); ?>

<table cellpadding="6" cellspacing="1" style="width:100%" border="0">

<tr>
    <th>QTY</th>
    <th>Item Description</th>
    <th style="text-align:right">Item Price</th>
    <th style="text-align:right">Sub-Total</th>
</tr>

<?php $i = 1; ?>

<?php foreach ($this->cart->contents() as $items): ?>

    <?php echo form_hidden($i.'[rowid]', $items['rowid']); ?>

    <tr>
        <td><?php echo form_input(array('name' => $i.'[qty]', 'value' => $items['qty'], 'maxlength' => 5, 'type' => 'text')); ?></td>
        <td><?php echo $items['name']; ?></td>
        <td><?php if ($this->cart->has_options($items['rowid']) == TRUE): ?>
```

```
                <p>
                    <?php foreach ($this->cart->product_options($items['rowid'])
                        <strong><?php echo $option_name; ?>:</strong> <?php e

                    <?php endforeach; ?>
                </p>

                <?php endif; ?>

            </td>
            <td style="text-align:right"><?php echo $this->cart->format_number($items['price']); ?></td>
            <td style="text-align:right">$<?php echo $this->cart->format_number($items['subtotal']); ?>
        </tr>

    <?php $i++; ?>

    <?php endforeach; ?>

    <tr>
        <td colspan="2"> </td>
        <td class="right"><strong>Total</strong></td>
        <td class="right">$<?php echo $this->cart->format_number($this->cart->total()); ?></td>
    </tr>

</table>

<p><?php echo form_submit('', 'Update your Cart'); ?></p>
```

Updating The Cart

To update the information in your cart, you must pass an array containing the Row ID and quantity to the `$this->cart->update()` function:

: If the quantity is set to zero, the item will be removed from the cart.

```
$data = array(
    'rowid' => 'b99ccdf16028f015540f341130b6d8ec',
    'qty'   => 3
);

$this->cart->update($data);

// Or a multi-dimensional array

$data = array(
    array(
        'rowid' => 'b99ccdf16028f015540f341130b6d8ec',
        'qty'   => 3
    ),
    array(
        'rowid' => 'xw82g9q3r495893iajdh473990rikw23',
        'qty'   => 4
    ),
    array(
        'rowid' => 'fh4kdkkkaoe30njgoe92rkdkkobec333',
```

```
                'qty'      => 2
            )
        );

$this->cart->update($data);
```

What is a Row ID?

The row ID is a unique identifier that is generated by the cart code when an item is added to the cart. The reason a unique ID is created is so that identical products with different options can be managed by the cart.

For example, let's say someone buys two identical t-shirts (same product ID), but in different sizes. The product ID (and other attributes) will be identical for both sizes because it's the same shirt. The only difference will be the size. The cart must therefore have a means of identifying this difference so that the two sizes of shirts can be managed independently. It does so by creating a unique "row ID" based on the product ID and any options associated with it.

In nearly all cases, updating the cart will be something the user does via the "view cart" page, so as a developer, it is unlikely that you will ever have to concern yourself with the "row ID", other than making sure your "view cart" page contains this information in a hidden form field, and making sure it gets passed to the update function when the update form is submitted. Please examine the construction of the "view cart" page above for more information.

Function Reference

`$this->cart->insert();`

Permits you to add items to the shopping cart, as outlined above.

`$this->cart->update();`

Permits you to update items in the shopping cart, as outlined above.

`$this->cart->remove(rowid);`

Allows you to remove an item from the shopping cart by passing it the rowid.

`$this->cart->total();`

Displays the total amount in the cart.

`$this->cart->total_items();`

Displays the total number of items in the cart.

`$this->cart->contents(boolean);`

Returns an array containing everything in the cart. You can sort the order, by which this is returned by passing it "true" where the contents will be sorted from newest to oldest, by leaving this function blank, you'll automatically just get first added to the basket to last added to the basket.

```
$this->cart->get_item($row_id);
```

Returns an array containing data for the item matching the specified row ID, or FALSE if no such item exists.

```
$this->cart->has_options($row_id);
```

Returns TRUE (boolean) if a particular row in the cart contains options. This function is designed to be used in a loop with `$this->cart->contents()`, since you must pass the rowid to this function, as shown in the Displaying the Cart example above.

```
$this->cart->product_options($row_id);
```

Returns an array of options for a particular product. This function is designed to be used in a loop with `$this->cart->contents()`, since you must pass the rowid to this function, as shown in the Displaying the Cart example above.

```
$this->cart->destroy();
```

Permits you to destroy the cart. This function will likely be called when you are finished processing the customer's order.

10.13.5 Config Class

The Config class provides a means to retrieve configuration preferences. These preferences can come from the default config file (application/config/config.php) or from your own custom config files.

: This class is initialized automatically by the system so there is no need to do it manually.

Page Contents

- Config Class
 - Anatomy of a Config File
 - Loading a Config File
 - * Manual Loading
 - * Auto-loading
 - Fetching Config Items
 - Setting a Config Item
 - Environments
 - Helper Functions
 - * `$this->config->site_url();`
 - * `$this->config->base_url();`
 - * `$this->config->system_url();`

Anatomy of a Config File

By default, CodeIgniter has one primary config file, located at application/config/config.php. If you open the file using your text editor you'll see that config items are stored in an array called `$config`.

You can add your own config items to this file, or if you prefer to keep your configuration items separate (assuming you even need config items), simply create your own file and save it in config folder.

: If you do create your own config files use the same format as the primary one, storing your items in an array called `$config`. CodeIgniter will intelligently manage these files so there will be no conflict even though the array has the same name (assuming an array index is not named the same as another).

Loading a Config File

: CodeIgniter automatically loads the primary config file (application/config/config.php), so you will only need to load a config file if you have created your own.

There are two ways to load a config file:

Manual Loading

To load one of your custom config files you will use the following function within the *controller* that needs it:

```
$this->config->load('filename');
```

Where filename is the name of your config file, without the .php file extension.

If you need to load multiple config files normally they will be merged into one master config array. Name collisions can occur, however, if you have identically named array indexes in different config files. To avoid collisions you can set the second parameter to TRUE and each config file will be stored in an array index corresponding to the name of the config file. Example:

```
// Stored in an array with this prototype: $this->config['blog_settings'] = $config  
$this->config->load('blog_settings', TRUE);
```

Please see the section entitled Fetching Config Items below to learn how to retrieve config items set this way.

The third parameter allows you to suppress errors in the event that a config file does not exist:

```
$this->config->load('blog_settings', FALSE, TRUE);
```

Auto-loading

If you find that you need a particular config file globally, you can have it loaded automatically by the system. To do this, open the **autoload.php** file, located at application/config/autoload.php, and add your config file as indicated in the file.

Fetching Config Items

To retrieve an item from your config file, use the following function:

```
$this->config->item('item name');
```

Where item name is the `$config` array index you want to retrieve. For example, to fetch your language choice you'll do this:

```
$lang = $this->config->item('language');
```

The function returns NULL if the item you are trying to fetch does not exist.

If you are using the second parameter of the `$this->config->load` function in order to assign your config items to a specific index you can retrieve it by specifying the index name in the second parameter of the `$this->config->item()` function. Example:

```
// Loads a config file named blog_settings.php and assigns it to an index named "blog_settings"
$this->config->load('blog_settings', TRUE);

// Retrieve a config item named site_name contained within the blog_settings array
$site_name = $this->config->item('site_name', 'blog_settings');

// An alternate way to specify the same item:
$blog_config = $this->config->item('blog_settings');
$site_name = $blog_config['site_name'];
```

Setting a Config Item

If you would like to dynamically set a config item or change an existing one, you can do so using:

```
$this->config->set_item('item_name', 'item_value');
```

Where `item_name` is the `$config` array index you want to change, and `item_value` is its value.

Environments

You may load different configuration files depending on the current environment. The `ENVIRONMENT` constant is defined in `index.php`, and is described in detail in the *Handling Environments* section.

To create an environment-specific configuration file, create or copy a configuration file in `application/config/{ENVIRONMENT}/{FILENAME}.php`

For example, to create a production-only config.php, you would:

1. Create the directory `application/config/production/`
2. Copy your existing `config.php` into the above directory
3. Edit `application/config/production/config.php` so it contains your production settings

When you set the `ENVIRONMENT` constant to 'production', the settings for your new production-only `config.php` will be loaded.

You can place the following configuration files in environment-specific folders:

- Default CodeIgniter configuration files
- Your own custom configuration files

: CodeIgniter always loads the global config file first (i.e., the one in `application/config/`), then tries to load the configuration files for the current environment. This means you are not obligated to place **all** of your configuration files in an environment folder. Only the files that change per environment. Additionally you don't have to copy **all** the config items in the environment config file. Only the config items that you wish to change for your environment. The config items declared in your environment folders always overwrite those in your global config files.

Helper Functions

The config class has the following helper functions:

```
$this->config->site_url();
```

This function retrieves the URL to your site, along with the “index” value you’ve specified in the config file.

```
$this->config->base_url();
```

This function retrieves the URL to your site, plus an optional path such as to a stylesheet or image.

The two functions above are normally accessed via the corresponding functions in the *URL Helper*.

```
$this->config->system_url();
```

This function retrieves the URL to your system folder.

10.13.6 Email Class

CodeIgniter’s robust Email Class supports the following features:

- Multiple Protocols: Mail, Sendmail, and SMTP
- TLS and SSL Encryption for SMTP
- Multiple recipients
- CC and BCCs
- HTML or Plaintext email
- Attachments
- Word wrapping
- Priorities
- BCC Batch Mode, enabling large email lists to be broken into small BCC batches.
- Email Debugging tools

Sending Email

Sending email is not only simple, but you can configure it on the fly or set your preferences in a config file.

Here is a basic example demonstrating how you might send email. Note: This example assumes you are sending the email from one of your *controllers*.

```
$this->load->library('email');

$this->email->from('your@example.com', 'Your Name');
$this->email->to('someone@example.com');
$this->email->cc('another@another-example.com');
$this->email->bcc('them@their-example.com');
```

```
$this->email->subject('Email Test');  
$this->email->message('Testing the email class.');
```

```
$this->email->send();
```

Setting Email Preferences

There are 21 different preferences available to tailor how your email messages are sent. You can either set them manually as described here, or automatically via preferences stored in your config file, described below:

Preferences are set by passing an array of preference values to the email initialize method. Here is an example of how you might set some preferences:

```
$config['protocol'] = 'sendmail';  
$config['mailpath'] = '/usr/sbin/sendmail';  
$config['charset'] = 'iso-8859-1';  
$config['wordwrap'] = TRUE;
```

```
$this->email->initialize($config);
```

: Most of the preferences have default values that will be used if you do not set them.

Setting Email Preferences in a Config File

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called the email.php, add the \$config array in that file. Then save the file at config/email.php and it will be used automatically. You will NOT need to use the `$this->email->initialize()` method if you save your preferences in a config file.

Email Preferences

The following is a list of all the preferences that can be set when sending email.

Preference	Default Value	Options	Description
user-agent	CodeIgniter	None	The “user agent”.
protocol	mail	mail, sendmail, or smtp	The mail sending protocol.
mail-path	/usr/sbin/sendmail	None	The server path to Sendmail.
smtp_host	No Default	None	SMTP Server Address.
smtp_user	No Default	None	SMTP Username.
smtp_pass	No Default	None	SMTP Password.
smtp_port	25	None	SMTP Port.
smtp_timeout	5	None	SMTP Timeout (in seconds).
smtp_keepalive	FALSE	TRUE or FALSE (boolean)	Enable persistent SMTP connections.
smtp_crypto	No Default	tls or ssl	SMTP Encryption
word-wrap	TRUE	TRUE or FALSE (boolean)	Enable word-wrap.
wrapchars	76		Character count to wrap at.
mailtype	text	text or html	Type of mail. If you send HTML email you must send it as a complete web page. Make sure you don’t have any relative links or relative image paths otherwise they will not work.
charset	<code>\$config['charset']</code>		Character set (utf-8, iso-8859-1, etc.).
validate	FALSE	TRUE or FALSE (boolean)	Whether to validate the email address.
priority	3	1, 2, 3, 4, 5	Email Priority. 1 = highest. 5 = lowest. 3 = normal.
crlf	<code>\n</code>	<code>“\r\n”</code> or <code>“\n”</code> or <code>“\r”</code>	Newline character. (Use <code>“\r\n”</code> to comply with RFC 822).
newline	<code>\n</code>	<code>“\r\n”</code> or <code>“\n”</code> or <code>“\r”</code>	Newline character. (Use <code>“\r\n”</code> to comply with RFC 822).
bcc_batch_mode	FALSE	TRUE or FALSE (boolean)	Enable BCC Batch Mode.
bcc_batch_size	250	None	Number of emails in each BCC batch.
dsn	FALSE	TRUE or FALSE (boolean)	Enable notify message from server

Email Methods Reference

`$this->email->from()`

Sets the email address and name of the person sending the email:

```
$this->email->from('you@example.com', 'Your Name');
```

You can also set a Return-Path, to help redirect undelivered mail:

```
$this->email->from('you@example.com', 'Your Name', 'returned_emails@example.com');
```

: Return-Path can't be used if you've configured 'smtp' as your protocol.

`$this->email->reply_to()`

Sets the reply-to address. If the information is not provided the information in the “from” method is used. Example:

```
$this->email->reply_to('you@example.com', 'Your Name');
```

`$this->email->to()`

Sets the email address(s) of the recipient(s). Can be a single email, a comma-delimited list or an array:

```
$this->email->to('someone@example.com');
```

```
$this->email->to('one@example.com, two@example.com, three@example.com');
```

```
$list = array('one@example.com', 'two@example.com', 'three@example.com');
```

```
$this->email->to($list);
```

`$this->email->cc()`

Sets the CC email address(s). Just like the “to”, can be a single email, a comma-delimited list or an array.

`$this->email->bcc()`

Sets the BCC email address(s). Just like the “to”, can be a single email, a comma-delimited list or an array.

`$this->email->subject()`

Sets the email subject:

```
$this->email->subject('This is my subject');
```

`$this->email->message()`

Sets the email message body:

```
$this->email->message('This is my message');
```

`$this->email->set_alt_message()`

Sets the alternative email message body:

```
$this->email->set_alt_message('This is the alternative message');
```

This is an optional message string which can be used if you send HTML formatted email. It lets you specify an alternative message with no HTML formatting which is added to the header string for people who do not accept HTML email. If you do not set your own message CodeIgniter will extract the message from your HTML email and strip the tags.

`$this->email->set_header()`

Appends additional headers to the e-mail:

```
$this->email->set_header('Header1', 'Value1');
$this->email->set_header('Header2', 'Value2');
```

`$this->email->clear()`

Initializes all the email variables to an empty state. This method is intended for use if you run the email sending method in a loop, permitting the data to be reset between cycles.

```
foreach ($list as $name => $address)
{
    $this->email->clear();

    $this->email->to($address);
    $this->email->from('your@example.com');
    $this->email->subject('Here is your info '.$name);
    $this->email->message('Hi '.$name.' Here is the info you requested.');
```

If you set the parameter to TRUE any attachments will be cleared as well:

```
$this->email->clear(TRUE);
```

`$this->email->send()`

The Email sending method. Returns boolean TRUE or FALSE based on success or failure, enabling it to be used conditionally:

```
if ( ! $this->email->send() )
{
    // Generate error
}
```

This method will automatically clear all parameters if the request was successful. To stop this behaviour pass FALSE:

```
if ( $this->email->send(FALSE) )
{
    // Parameters won't be cleared
}
```

: In order to use the `print_debugger()` method, you need to avoid clearing the email parameters.

`$this->email->attach()`

Enables you to send an attachment. Put the file path/name in the first parameter. Note: Use a file path, not a URL. For multiple attachments use the method multiple times. For example:

```
$this->email->attach('/path/to/photo1.jpg');
$this->email->attach('/path/to/photo2.jpg');
$this->email->attach('/path/to/photo3.jpg');
```

To use the default disposition (attachment), leave the second parameter blank, otherwise use a custom disposition:

```
$this->email->attach('image.jpg', 'inline');
```

If you'd like to use a custom file name, you can use the third parameter:

```
$this->email->attach('filename.pdf', 'attachment', 'report.pdf');
```

If you need to use a buffer string instead of a real - physical - file you can use the first parameter as buffer, the third parameter as file name and the fourth parameter as mime-type:

```
$this->email->attach($buffer, 'attachment', 'report.pdf', 'application/pdf');
```

`$this->email->print_debugger()`

Returns a string containing any server messages, the email headers, and the email message. Useful for debugging.

You can optionally specify which parts of the message should be printed. Valid options are: **headers**, **subject**, **body**.

Example:

```
// You need to pass FALSE while sending in order for the email data
// to not be cleared - if that happens, print_debugger() would have
// nothing to output.
$this->email->send(FALSE);

// Will only print the email headers, excluding the message subject and body
$this->email->print_debugger(array('headers'));
```

: By default, all of the raw data will be printed.

Overriding Word Wrapping

If you have word wrapping enabled (recommended to comply with RFC 822) and you have a very long link in your email it can get wrapped too, causing it to become un-clickable by the person receiving it. CodeIgniter lets you manually override word wrapping within part of your message like this:

```
The text of your email that
gets wrapped normally.
```

```
{unwrap}http://example.com/a_long_link_that_should_not_be_wrapped.html{/unwrap}
```

```
More text that will be
wrapped normally.
```

Place the item you do not want word-wrapped between: `{unwrap} {/unwrap}`

10.13.7 Encryption Class

The Encryption Class provides two-way data encryption. It uses a scheme that either compiles the message using a randomly hashed bitwise XOR encoding scheme, or is encrypted using the Mcrypt library. If Mcrypt is not available on your server the encoded message will still provide a reasonable degree of security for encrypted sessions or other such “light” purposes. If Mcrypt is available, you’ll be provided with a high degree of security appropriate for storage.

Setting your Key

A *key* is a piece of information that controls the cryptographic process and permits an encrypted string to be decoded. In fact, the key you chose will provide the **only** means to decode data that was encrypted with that key, so not only must you choose the key carefully, you must never change it if you intend use it for persistent data.

It goes without saying that you should guard your key carefully. Should someone gain access to your key, the data will be easily decoded. If your server is not totally under your control it’s impossible to ensure key security so you may want to think carefully before using it for anything that requires high security, like storing credit card numbers.

To take maximum advantage of the encryption algorithm, your key should be 32 characters in length (256 bits). The key should be as random a string as you can concoct, with numbers and uppercase and lowercase letters. Your key should **not** be a simple text string. In order to be cryptographically secure it needs to be as random as possible.

Your key can be either stored in your **application/config/config.php**, or you can design your own storage mechanism and pass the key dynamically when encoding/decoding.

To save your key to your **application/config/config.php**, open the file and set:

```
$config['encryption_key'] = "YOUR KEY";
```

Message Length

It’s important for you to know that the encoded messages the encryption function generates will be approximately 2.6 times longer than the original message. For example, if you encrypt the string “my super secret data”, which is 21 characters in length, you’ll end up with an encoded string that is roughly 55 characters (we say “roughly” because the encoded string length increments in 64 bit clusters, so it’s not exactly linear). Keep this information in mind when selecting your data storage mechanism. Cookies, for example, can only hold 4K of information.

Initializing the Class

Like most other classes in CodeIgniter, the Encryption class is initialized in your controller using the **\$this->load->library** function:

```
$this->load->library('encrypt');
```

Once loaded, the Encrypt library object will be available using: **\$this->encrypt**

\$this->encrypt->encode()

Performs the data encryption and returns it as a string. Example:

```
$msg = 'My secret message';

$encrypted_string = $this->encrypt->encode($msg);
```

You can optionally pass your encryption key via the second parameter if you don't want to use the one in your config file:

```
$msg = 'My secret message';
$key = 'super-secret-key';

$encrypted_string = $this->encrypt->encode($msg, $key);
```

`$this->encrypt->decode()`

Decrypts an encoded string. Example:

```
$encrypted_string = 'APANtByIGI1BpVXZTJgcsAG8GZl8pdwwa84';

$plaintext_string = $this->encrypt->decode($encrypted_string);
```

You can optionally pass your encryption key via the second parameter if you don't want to use the one in your config file:

```
$msg = 'My secret message';
$key = 'super-secret-key';

$encrypted_string = $this->encrypt->decode($msg, $key);
```

`$this->encrypt->set_cipher();`

Permits you to set an Mcrypt cipher. By default it uses **MCRYPT_RIJNDAEL_256**. Example:

```
$this->encrypt->set_cipher(MCRYPT_BLOWFISH);
```

Please visit php.net for a list of [available ciphers](#).

If you'd like to manually test whether your server supports Mcrypt you can use:

```
echo ( ! function_exists('mcrypt_encrypt')) ? 'Nope' : 'Yup';
```

`$this->encrypt->set_mode();`

Permits you to set an Mcrypt mode. By default it uses **MCRYPT_MODE_CBC**. Example:

```
$this->encrypt->set_mode(MCRYPT_MODE_CFB);
```

Please visit php.net for a list of [available modes](#).

`$this->encrypt->encode_from_legacy($orig_data, $legacy_mode = MCRYPT_MODE_ECB, $key = '');`

Enables you to re-encode data that was originally encrypted with CodeIgniter 1.x to be compatible with the Encryption library in CodeIgniter 2.x. It is only necessary to use this method if you have encrypted data stored permanently such as in a file or database and are on a server that supports Mcrypt. "Light" use encryption such as encrypted session data or transitory encryptedflashdata require no intervention on your part. However, existing encrypted Sessions will be destroyed since data encrypted prior to 2.x will not be decoded.

: Why only a method to re-encode the data instead of maintaining legacy methods for both encoding and decoding? The algorithms in the Encryption library have improved in CodeIgniter 2.x both for performance and security, and we do not wish to encourage continued use of the older methods. You can of course extend the Encryption

library if you wish and replace the new methods with the old and retain seamless compatibility with CodeIgniter 1.x encrypted data, but this a decision that a developer should make cautiously and deliberately, if at all.

```
$new_data = $this->encrypt->encode_from_legacy($old_encrypted_string);
```

Parameter	Default	Description
\$orig_data	n/a	The original encrypted data from CodeIgniter 1.x's Encryption library
\$legacy_mode	MCRYPT_MODE_ECB	The encrypt mode that was used to generate the original encrypted data. CodeIgniter 1.x's default was MCRYPT_MODE_ECB, and it will assume that to be the case unless overridden by this parameter.
\$key	n/a	The encryption key. This it typically specified in your config file as outlined above.

10.13.8 File Uploading Class

CodeIgniter's File Uploading Class permits files to be uploaded. You can set various preferences, restricting the type and size of the files.

The Process

Uploading a file involves the following general process:

- An upload form is displayed, allowing a user to select a file and upload it.
- When the form is submitted, the file is uploaded to the destination you specify.
- Along the way, the file is validated to make sure it is allowed to be uploaded based on the preferences you set.
- Once uploaded, the user will be shown a success message.

To demonstrate this process here is brief tutorial. Afterward you'll find reference information.

Creating the Upload Form

Using a text editor, create a form called `upload_form.php`. In it, place this code and save it to your **application/views/** directory:

```
<html>
<head>
<title>Upload Form</title>
</head>
<body>

<?php echo $error;?>

<?php echo form_open_multipart('upload/do_upload');?>

<input type="file" name="userfile" size="20" />

<br /><br />

<input type="submit" value="upload" />

</form>
```

```
</body>
</html>
```

You'll notice we are using a form helper to create the opening form tag. File uploads require a multipart form, so the helper creates the proper syntax for you. You'll also notice we have an `$error` variable. This is so we can show error messages in the event the user does something wrong.

The Success Page

Using a text editor, create a form called `upload_success.php`. In it, place this code and save it to your **application/views/** directory:

```
<html>
<head>
<title>Upload Form</title>
</head>
<body>

<h3>Your file was successfully uploaded!</h3>

<ul>
<?php foreach ($upload_data as $item => $value):?>
<li><?php echo $item;?: <?php echo $value;?></li>
<?php endforeach; ?>
</ul>

<p><?php echo anchor('upload', 'Upload Another File!'); ?></p>

</body>
</html>
```

The Controller

Using a text editor, create a controller called `Upload.php`. In it, place this code and save it to your **application/controllers/** directory:

```
<?php

class Upload extends CI_Controller {

    public function __construct()
    {
        parent::__construct();
        $this->load->helper(array('form', 'url'));
    }

    public function index()
    {
        $this->load->view('upload_form', array('error' => ' ' ));
    }

    public function do_upload()
    {
        $config['upload_path']           = './uploads/';
        $config['allowed_types']         = 'gif|jpg|png';
```

```

$config['max_size']           = 100;
$config['max_width']         = 1024;
$config['max_height']        = 768;

$this->load->library('upload', $config);

if ( ! $this->upload->do_upload() )
{
    $error = array('error' => $this->upload->display_errors());

    $this->load->view('upload_form', $error);
}
else
{
    $data = array('upload_data' => $this->upload->data());

    $this->load->view('upload_success', $data);
}
}
?>

```

The Upload Directory

You'll need a destination directory for your uploaded images. Create a directory at the root of your CodeIgniter installation called uploads and set its file permissions to 777.

Try it!

To try your form, visit your site using a URL similar to this one:

`example.com/index.php/upload/`

You should see an upload form. Try uploading an image file (either a jpg, gif, or png). If the path in your controller is correct it should work.

Reference Guide

Initializing the Upload Class

Like most other classes in CodeIgniter, the Upload class is initialized in your controller using the `$this->load->library()` method:

```
$this->load->library('upload');
```

Once the Upload class is loaded, the object will be available using: `$this->upload`

Setting Preferences

Similar to other libraries, you'll control what is allowed to be upload based on your preferences. In the controller you built above you set the following preferences:

```
$config['upload_path'] = './uploads/';
$config['allowed_types'] = 'gif|jpg|png';
$config['max_size']      = '100';
$config['max_width']    = '1024';
$config['max_height']   = '768';

$this->load->library('upload', $config);

// Alternately you can set preferences by calling the ``initialize()`` method. Useful if you auto-load
$this->upload->initialize($config);
```

The above preferences should be fairly self-explanatory. Below is a table describing all available preferences.

Preferences

The following preferences are available. The default value indicates what will be used if you do not specify that preference.

Preference	Default Value	Options	Description
upload_path	None	None	The path to the directory where the upload should be placed. The directory must be writable and the path can be absolute or relative.
allowed_types	None	None	The mime types corresponding to the types of files you allow to be uploaded. Usually the file extension can be used as the mime type. Separate multiple types with a pipe.
file_name	None	Desired file name	If set CodeIgniter will rename the uploaded file to this name. The extension provided in the file name must also be an allowed file type. If no extension is provided in the original file_name will be used.
file_ext_tolower	FALSE	TRUE/FALSE (boolean)	If set to TRUE, the file extension will be forced to lower case
overwrite	FALSE	TRUE/FALSE (boolean)	If set to true, if a file with the same name as the one you are uploading exists, it will be overwritten. If set to false, a number will be appended to the filename if another with the same name exists.
max_size	0	None	The maximum size (in kilobytes) that the file can be. Set to zero for no limit. Note: Most PHP installations have their own limit, as specified in the php.ini file. Usually 2 MB (or 2048 KB) by default.
max_width	0	None	The maximum width (in pixels) that the image can be. Set to zero for no limit.
max_height	0	None	The maximum height (in pixels) that the image can be. Set to zero for no limit.
min_width	0	None	The minimum width (in pixels) that the image can be. Set to zero for no limit.
min_height	0	None	The minimum height (in pixels) that the image can be. Set to zero for no limit.
max_filename	0	None	The maximum length that a file name can be. Set to zero for no limit.
max_filename_increment	100	None	When overwrite is set to FALSE, use this to set the maximum filename increment for CodeIgniter to append to the filename.
encrypt_name	FALSE	TRUE/FALSE (boolean)	If set to TRUE the file name will be converted to a random encrypted string. This can be useful if you would like the file saved with a name that can not be discerned by the person uploading it.
remove_spaces	TRUE	TRUE/FALSE (boolean)	If set to TRUE, any spaces in the file name will be converted to underscores. This is recommended.
detect_mime	TRUE	TRUE/FALSE (boolean)	If set to TRUE, a server side detection of the file type will be performed to avoid code injection attacks. DO NOT disable this option unless you have no other option as that would cause a security risk.
mod_mime_fix	TRUE	TRUE/FALSE (boolean)	If set to TRUE, multiple filename extensions will be suffixed with an underscore in order to avoid triggering Apache mod_mime . DO NOT turn off this option if your upload directory is public, as this is a security risk.

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called the upload.php, add the \$config array in that file. Then save the file in: **config/upload.php** and it will be used automatically. You will NOT need to use the `$this->upload->initialize()` method if you save your preferences in a config file.

Class Reference

The following methods are available:

`$this->upload->do_upload()`

Performs the upload based on the preferences you've set.

: By default the upload routine expects the file to come from a form field called `userfile`, and the form must be of type `"multipart"`.

```
<form method="post" action="some_action" enctype="multipart/form-data" />
```

If you would like to set your own field name simply pass its value to the `do_upload()` method:

```
$field_name = "some_field_name";  
$this->upload->do_upload($field_name);
```

`$this->upload->display_errors()`

Retrieves any error messages if the `do_upload()` method returned false. The method does not echo automatically, it returns the data so you can assign it however you need.

Formatting Errors By default the above method wraps any errors within `<p>` tags. You can set your own delimiters like this:

```
$this->upload->display_errors(' <p>', ' </p>');
```

`$this->upload->data()`

This is a helper method that returns an array containing all of the data related to the file you uploaded. Here is the array prototype:

```
Array  
(  
    [file_name]      => mypic.jpg  
    [file_type]      => image/jpeg  
    [file_path]      => /path/to/your/upload/  
    [full_path]      => /path/to/your/upload/jpg.jpg  
    [raw_name]       => mypic  
    [orig_name]      => mypic.jpg  
    [client_name]    => mypic.jpg  
    [file_ext]       => .jpg  
    [file_size]      => 22.2  
    [is_image]       => 1  
    [image_width]    => 800  
    [image_height]   => 600  
    [image_type]     => jpeg  
    [image_size_str] => width="800" height="200"  
)
```

To return one element from the array:

```
$this->upload->data('file_name');           // Returns: mypic.jpg
```

Explanation Here is an explanation of the above array items.

Item Description **file_name** The name of the file that was uploaded including the file extension. **file_type** The file's Mime type **file_path** The absolute server path to the file **full_path** The absolute server path including the file name **raw_name** The file name without the extension **orig_name** The original file name. This is only useful if you use the encrypted name option. **client_name** The file name as supplied by the client user agent, prior to any file name preparation or incrementing. **file_ext** The file extension with period **file_size** The file size in kilobytes **is_image** Whether the file is an image or not. 1 = image. 0 = not. **image_width** Image width. **image_height** Image height **image_type** Image type. Typically the file extension without the period. **image_size_str** A string containing the width and height. Useful to put into an image tag.

10.13.9 Form Validation

CodeIgniter provides a comprehensive form validation and data prepping class that helps minimize the amount of code you'll write.

Overview

Before explaining CodeIgniter's approach to data validation, let's describe the ideal scenario:

1. A form is displayed.
2. You fill it in and submit it.
3. If you submitted something invalid, or perhaps missed a required item, the form is redisplayed containing your data along with an error message describing the problem.

4. This process continues until you have submitted a valid form.

On the receiving end, the script must:

1. Check for required data.
2. Verify that the data is of the correct type, and meets the correct criteria. For example, if a username is submitted it must be validated to contain only permitted characters. It must be of a minimum length, and not exceed a maximum length. The username can't be someone else's existing username, or perhaps even a reserved word. Etc.
3. Sanitize the data for security.
4. Pre-format the data if needed (Does the data need to be trimmed? HTML encoded? Etc.)
5. Prep the data for insertion in the database.

Although there is nothing terribly complex about the above process, it usually requires a significant amount of code, and to display error messages, various control structures are usually placed within the form HTML. Form validation, while simple to create, is generally very messy and tedious to implement.

Form Validation Tutorial

What follows is a “hands on” tutorial for implementing CodeIgniter's Form Validation.

In order to implement form validation you'll need three things:

1. A *View* file containing a form.
2. A *View* file containing a “success” message to be displayed upon successful submission.
3. A *controller* method to receive and process the submitted data.

Let's create those three things, using a member sign-up form as the example.

The Form

Using a text editor, create a form called `myform.php`. In it, place this code and save it to your `application/views/` folder:

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<?php echo validation_errors(); ?>

<?php echo form_open('form'); ?>

<h5>Username</h5>
<input type="text" name="username" value="" size="50" />

<h5>Password</h5>
<input type="text" name="password" value="" size="50" />

<h5>Password Confirm</h5>
<input type="text" name="passconf" value="" size="50" />

<h5>Email Address</h5>
<input type="text" name="email" value="" size="50" />
```

```
<div><input type="submit" value="Submit" /></div>

</form>

</body>
</html>
```

The Success Page

Using a text editor, create a form called `formsuccess.php`. In it, place this code and save it to your `application/views/` folder:

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<h3>Your form was successfully submitted!</h3>

<p><?php echo anchor('form', 'Try it again!'); ?></p>

</body>
</html>
```

The Controller

Using a text editor, create a controller called `form.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}
```

Try it!

To try your form, visit your site using a URL similar to this one:

example.com/index.php/form/

If you submit the form you should simply see the form reload. That's because you haven't set up any validation rules yet.

Since you haven't told the Form Validation class to validate anything yet, it returns FALSE (boolean false) by default. "The run()" method only returns TRUE if it has successfully applied your rules without any of them failing.

Explanation

You'll notice several things about the above pages:

The form (myform.php) is a standard web form with a couple exceptions:

1. It uses a form helper to create the form opening. Technically, this isn't necessary. You could create the form using standard HTML. However, the benefit of using the helper is that it generates the action URL for you, based on the URL in your config file. This makes your application more portable in the event your URLs change.
2. At the top of the form you'll notice the following function call:

```
<?php echo validation_errors(); ?>
```

This function will return any error messages sent back by the validator. If there are no messages it returns an empty string.

The controller (form.php) has one method: `index()`. This method initializes the validation class and loads the form helper and URL helper used by your view files. It also runs the validation routine. Based on whether the validation was successful it either presents the form or the success page.

Setting Validation Rules

CodeIgniter lets you set as many validation rules as you need for a given field, cascading them in order, and it even lets you prep and pre-process the field data at the same time. To set validation rules you will use the `set_rules()` method:

```
$this->form_validation->set_rules();
```

The above method takes **three** parameters as input:

1. The field name - the exact name you've given the form field.
2. A "human" name for this field, which will be inserted into the error message. For example, if your field is named "user" you might give it a human name of "Username".
3. The validation rules for this form field.

: If you would like the field name to be stored in a language file, please see *Translating Field Names*.

Here is an example. In your controller (form.php), add this code just below the validation initialization method:

```
$this->form_validation->set_rules('username', 'Username', 'required');
$this->form_validation->set_rules('password', 'Password', 'required');
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
$this->form_validation->set_rules('email', 'Email', 'required');
```

Your controller should now look like this:

```
<?php

class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        $this->form_validation->set_rules('username', 'Username', 'required');
        $this->form_validation->set_rules('password', 'Password', 'required');
        $this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
        $this->form_validation->set_rules('email', 'Email', 'required');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}
```

Now submit the form with the fields blank and you should see the error messages. If you submit the form with all the fields populated you'll see your success page.

: The form fields are not yet being re-populated with the data when there is an error. We'll get to that shortly.

Setting Rules Using an Array

Before moving on it should be noted that the rule setting method can be passed an array if you prefer to set all your rules in one action. If you use this approach, you must name your array keys as indicated:

```
$config = array(
    array(
        'field' => 'username',
        'label' => 'Username',
        'rules' => 'required'
    ),
    array(
        'field' => 'password',
        'label' => 'Password',
        'rules' => 'required'
    ),
    array(
        'field' => 'passconf',
        'label' => 'Password Confirmation',
        'rules' => 'required'
    ),
    array(
        'field' => 'email',
        'label' => 'Email',
        'rules' => 'required'
    )
);
```

```

    )
);

$this->form_validation->set_rules($config);

```

Cascading Rules

CodeIgniter lets you pipe multiple rules together. Let's try it. Change your rules in the third parameter of rule setting method, like this:

```

$this->form_validation->set_rules('username', 'Username', 'required|min_length[5]|max_length[12]|is_unique[users.username]');
$this->form_validation->set_rules('password', 'Password', 'required');
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'required|matches[password]');
$this->form_validation->set_rules('email', 'Email', 'required|valid_email|is_unique[users.email]');

```

The above code sets the following rules:

1. The username field be no shorter than 5 characters and no longer than 12.
2. The password field must match the password confirmation field.
3. The email field must contain a valid email address.

Give it a try! Submit your form without the proper data and you'll see new error messages that correspond to your new rules. There are numerous rules available which you can read about in the validation reference.

: You can also pass an array of rules to `set_rules()`, instead of a string. Example:

```

$this->form_validation->set_rules('username', 'Username', array('required', 'min_length[5]'));

```

Prepping Data

In addition to the validation method like the ones we used above, you can also prep your data in various ways. For example, you can set up rules like this:

```

$this->form_validation->set_rules('username', 'Username', 'trim|required|min_length[5]|max_length[12]|xss_clean');
$this->form_validation->set_rules('password', 'Password', 'trim|required|md5');
$this->form_validation->set_rules('passconf', 'Password Confirmation', 'trim|required|matches[password]');
$this->form_validation->set_rules('email', 'Email', 'trim|required|valid_email');

```

In the above example, we are “trimming” the fields, converting the password to MD5, and running the username through the `xss_clean()` method, which removes malicious data.

Any native PHP function that accepts one parameter can be used as a rule, like `htmlspecialchars`, `trim`, `md5`, etc.

: You will generally want to use the prepping functions **after** the validation rules so if there is an error, the original data will be shown in the form.

Re-populating the form

Thus far we have only been dealing with errors. It's time to repopulate the form field with the submitted data. CodeIgniter offers several helper functions that permit you to do this. The one you will use most commonly is:

```
set_value('field name')
```

Open your myform.php view file and update the **value** in each field using the `set_value()` function:

Don't forget to include each field name in the “`set_value()`” functions!

```
<html>
<head>
<title>My Form</title>
</head>
<body>

<?php echo validation_errors(); ?>

<?php echo form_open('form'); ?>

<h5>Username</h5>
<input type="text" name="username" value="<?php echo set_value('username'); ?>" size="50" />

<h5>Password</h5>
<input type="text" name="password" value="<?php echo set_value('password'); ?>" size="50" />

<h5>Password Confirm</h5>
<input type="text" name="passconf" value="<?php echo set_value('passconf'); ?>" size="50" />

<h5>Email Address</h5>
<input type="text" name="email" value="<?php echo set_value('email'); ?>" size="50" />

<div><input type="submit" value="Submit" /></div>

</form>

</body>
</html>
```

Now reload your page and submit the form so that it triggers an error. Your form fields should now be re-populated

: The *Class Reference* section below contains functions that permit you to re-populate `<select>` menus, radio buttons, and checkboxes.

Important Note: If you use an array as the name of a form field, you must supply it as an array to the function. Example:

```
<input type="text" name="colors[]" value="<?php echo set_value('colors[]'); ?>" size="50" />
```

For more info please see the *Using Arrays as Field Names* section below.

Callbacks: Your own Validation Methods

The validation system supports callbacks to your own validation methods. This permits you to extend the validation class to meet your needs. For example, if you need to run a database query to see if the user is choosing a unique username, you can create a callback method that does that. Let's create an example of this.

In your controller, change the “username” rule to this:

```
$this->form_validation->set_rules('username', 'Username', 'callback_username_check');
```

Then add a new method called `username_check()` to your controller. Here's how your controller should now look:

```
<?php
```

```
class Form extends CI_Controller {

    public function index()
    {
        $this->load->helper(array('form', 'url'));

        $this->load->library('form_validation');

        $this->form_validation->set_rules('username', 'Username', 'callback_username_check');
        $this->form_validation->set_rules('password', 'Password', 'required');
        $this->form_validation->set_rules('passconf', 'Password Confirmation', 'required');
        $this->form_validation->set_rules('email', 'Email', 'required|is_unique[users.email]');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }

    public function username_check($str)
    {
        if ($str == 'test')
        {
            $this->form_validation->set_message('username_check', 'The {field} field can');
            return FALSE;
        }
        else
        {
            return TRUE;
        }
    }
}
```

Reload your form and submit it with the word “test” as the username. You can see that the form field data was passed to your callback method for you to process.

To invoke a callback just put the method name in a rule, with “callback_” as the rule **prefix**. If you need to receive an extra parameter in your callback method, just add it normally after the method name between square brackets, as in: “callback_foo**[bar]**”, then it will be passed as the second argument of your callback method.

: You can also process the form data that is passed to your callback and return it. If your callback returns anything other than a boolean TRUE/FALSE it is assumed that the data is your newly processed form data.

Setting Error Messages

All of the native error messages are located in the following language file: **system/language/english/form_validation_lang.php**

To set your own custom message you can either edit that file, or use the following method:

```
$this->form_validation->set_message('rule', 'Error Message');
```

Where rule corresponds to the name of a particular rule, and Error Message is the text you would like displayed.

If you'd like to include a field's "human" name, or the optional parameter some rules allow for (such as max_length), you can add the **{field}** and **{param}** tags to your message, respectively:

```
$this->form_validation->set_message('min_length', '{field} must have at least {param} characters.');
```

On a field with the human name Username and a rule of min_length[5], an error would display: "Username must have at least 5 characters."

: The old *sprintf()* method of using *%s* in your error messages will still work, however it will override the tags above. You should use one or the other.

In the callback rule example above, the error message was set by passing the name of the method (without the "callback_" prefix):

```
$this->form_validation->set_message('username_check')
```

Translating Field Names

If you would like to store the "human" name you passed to the `set_rules()` method in a language file, and therefore make the name able to be translated, here's how:

First, prefix your "human" name with **lang:**, as in this example:

```
$this->form_validation->set_rules('first_name', 'lang:first_name', 'required');
```

Then, store the name in one of your language file arrays (without the prefix):

```
$lang['first_name'] = 'First Name';
```

: If you store your array item in a language file that is not loaded automatically by CI, you'll need to remember to load it in your controller using:

```
$this->lang->load('file_name');
```

See the *Language Class* page for more info regarding language files.

Changing the Error Delimiters

By default, the Form Validation class adds a paragraph tag (<p>) around each error message shown. You can either change these delimiters globally, individually, or change the defaults in a config file.

1. **Changing delimiters Globally** To globally change the error delimiters, in your controller method, just after loading the Form Validation class, add this:

```
$this->form_validation->set_error_delimiters('<div class="error">', '</div>');
```

In this example, we've switched to using div tags.

2. **Changing delimiters Individually** Each of the two error generating functions shown in this tutorial can be supplied their own delimiters as follows:

```
<?php echo form_error('field name', '<div class="error">', '</div>'); ?>
```

Or:

```
<?php echo validation_errors('<div class="error">', '</div>'); ?>
```

3. **Set delimiters in a config file** You can add your error delimiters in application/config/form_validation.php as follows:

```
$config['error_prefix'] = '<div class="error_prefix">';
$config['error_suffix'] = '</div>';
```

Showing Errors Individually

If you prefer to show an error message next to each form field, rather than as a list, you can use the `form_error()` function.

Try it! Change your form so that it looks like this:

```
<h5>Username</h5>
<?php echo form_error('username'); ?>
<input type="text" name="username" value="<?php echo set_value('username'); ?>" size="50" />

<h5>Password</h5>
<?php echo form_error('password'); ?>
<input type="text" name="password" value="<?php echo set_value('password'); ?>" size="50" />

<h5>Password Confirm</h5>
<?php echo form_error('passconf'); ?>
<input type="text" name="passconf" value="<?php echo set_value('passconf'); ?>" size="50" />

<h5>Email Address</h5>
<?php echo form_error('email'); ?>
<input type="text" name="email" value="<?php echo set_value('email'); ?>" size="50" />
```

If there are no errors, nothing will be shown. If there is an error, the message will appear.

: If you use an array as the name of a form field, you must supply it as an array to the function. Example:

```
<?php echo form_error('options[size]'); ?>
<input type="text" name="options[size]" value="<?php echo set_value("options[size]"); ?>" size="50" />
```

For more info please see the *Using Arrays as Field Names* section below.

Validating an Array (other than \$_POST)

Sometimes you may want to validate an array that does not originate from `$_POST` data.

In this case, you can specify the array to be validated:

```
$data = array(
    'username' => 'johndoe',
    'password' => 'mypassword',
    'passconf' => 'mypassword'
);
```

```
$this->form_validation->set_data($data);
```

Creating validation rules, running the validation, and retrieving error messages works the same whether you are validating `$_POST` data or an array.

: If you want to validate more than one array during a single execution, then you should call the `reset_validation()` method before setting up rules and validating the new array.

For more info please see the *Class Reference* section below.

Saving Sets of Validation Rules to a Config File

A nice feature of the Form Validation class is that it permits you to store all your validation rules for your entire application in a config file. You can organize these rules into “groups”. These groups can either be loaded automatically when a matching controller/method is called, or you can manually call each set as needed.

How to save your rules

To store your validation rules, simply create a file named `form_validation.php` in your `application/config/` folder. In that file you will place an array named `$config` with your rules. As shown earlier, the validation array will have this prototype:

```
$config = array(
    array(
        'field' => 'username',
        'label' => 'Username',
        'rules' => 'required'
    ),
    array(
        'field' => 'password',
        'label' => 'Password',
        'rules' => 'required'
    ),
    array(
        'field' => 'passconf',
        'label' => 'Password Confirmation',
        'rules' => 'required'
    ),
    array(
        'field' => 'email',
        'label' => 'Email',
        'rules' => 'required'
    )
);
```

Your validation rule file will be loaded automatically and used when you call the `run()` method.

Please note that you **MUST** name your `$config` array.

Creating Sets of Rules

In order to organize your rules into “sets” requires that you place them into “sub arrays”. Consider the following example, showing two sets of rules. We’ve arbitrarily called these two rules “signup” and “email”. You can name your rules anything you want:

```

$config = array(
    'signup' => array(
        array(
            'field' => 'username',
            'label' => 'Username',
            'rules' => 'required'
        ),
        array(
            'field' => 'password',
            'label' => 'Password',
            'rules' => 'required'
        ),
        array(
            'field' => 'passconf',
            'label' => 'Password Confirmation',
            'rules' => 'required'
        ),
        array(
            'field' => 'email',
            'label' => 'Email',
            'rules' => 'required'
        )
    ),
    'email' => array(
        array(
            'field' => 'emailaddress',
            'label' => 'EmailAddress',
            'rules' => 'required|valid_email'
        ),
        array(
            'field' => 'name',
            'label' => 'Name',
            'rules' => 'required|alpha'
        ),
        array(
            'field' => 'title',
            'label' => 'Title',
            'rules' => 'required'
        ),
        array(
            'field' => 'message',
            'label' => 'MessageBody',
            'rules' => 'required'
        )
    )
);

```

Calling a Specific Rule Group

In order to call a specific group, you will pass its name to the `run()` method. For example, to call the `signup` rule you will do this:

```

if ($this->form_validation->run('signup') == FALSE)
{
    $this->load->view('myform');
}
else

```

```
{
    $this->load->view('formsuccess');
}
```

Associating a Controller Method with a Rule Group

An alternate (and more automatic) method of calling a rule group is to name it according to the controller class/method you intend to use it with. For example, let's say you have a controller named Member and a method named signup. Here's what your class might look like:

```
<?php

class Member extends CI_Controller {

    public function signup()
    {
        $this->load->library('form_validation');

        if ($this->form_validation->run() == FALSE)
        {
            $this->load->view('myform');
        }
        else
        {
            $this->load->view('formsuccess');
        }
    }
}
```

In your validation config file, you will name your rule group member/signup:

```
$config = array(
    'member/signup' => array(
        array(
            'field' => 'username',
            'label' => 'Username',
            'rules' => 'required'
        ),
        array(
            'field' => 'password',
            'label' => 'Password',
            'rules' => 'required'
        ),
        array(
            'field' => 'passconf',
            'label' => 'PasswordConfirmation',
            'rules' => 'required'
        ),
        array(
            'field' => 'email',
            'label' => 'Email',
            'rules' => 'required'
        )
    )
);
```

When a rule group is named identically to a controller class/method it will be used automatically when the `run()`

method is invoked from that class/method.

Using Arrays as Field Names

The Form Validation class supports the use of arrays as field names. Consider this example:

```
<input type="text" name="options[]" value="" size="50" />
```

If you do use an array as a field name, you must use the EXACT array name in the *Helper Functions* that require the field name, and as your Validation Rule field name.

For example, to set a rule for the above field you would use:

```
$this->form_validation->set_rules('options[]', 'Options', 'required');
```

Or, to show an error for the above field you would use:

```
<?php echo form_error('options[]'); ?>
```

Or to re-populate the field you would use:

```
<input type="text" name="options[]" value="<?php echo set_value('options[]'); ?>" size="50" />
```

You can use multidimensional arrays as field names as well. For example:

```
<input type="text" name="options[size]" value="" size="50" />
```

Or even:

```
<input type="text" name="sports[nba][basketball]" value="" size="50" />
```

As with our first example, you must use the exact array name in the helper functions:

```
<?php echo form_error('sports[nba][basketball]'); ?>
```

If you are using checkboxes (or other fields) that have multiple options, don't forget to leave an empty bracket after each option, so that all selections will be added to the POST array:

```
<input type="checkbox" name="options[]" value="red" />
<input type="checkbox" name="options[]" value="blue" />
<input type="checkbox" name="options[]" value="green" />
```

Or if you use a multidimensional array:

```
<input type="checkbox" name="options[color][]" value="red" />
<input type="checkbox" name="options[color][]" value="blue" />
<input type="checkbox" name="options[color][]" value="green" />
```

When you use a helper function you'll include the bracket as well:

```
<?php echo form_error('options[color][]'); ?>
```

Rule Reference

The following is a list of all the native rules that are available to use:

Rule	Parameter	Description	Example
required	No	Returns FALSE if the form element is empty.	
matches	Yes	Returns FALSE if the form element does not match the one in the parameter.	matches[form_item]
differs	Yes	Returns FALSE if the form element does not differ from the one in the parameter.	differs[form_item]
is_unique	Yes	Returns FALSE if the form element is not unique to the table and field name in the parameter. Note: This rule requires <i>Query Builder</i> to be enabled in order to work.	is_unique[table.field]
min_length	Yes	Returns FALSE if the form element is shorter than the parameter value.	min_length[3]
max_length	Yes	Returns FALSE if the form element is longer than the parameter value.	max_length[12]
exact_length	Yes	Returns FALSE if the form element is not exactly the parameter value.	exact_length[8]
greater_than	Yes	Returns FALSE if the form element is less than or equal to the parameter value or not numeric.	greater_than[8]
greater_than_equal_to	Yes	Returns FALSE if the form element is less than the parameter value, or not numeric.	greater_than_equal_to[8]
less_than	Yes	Returns FALSE if the form element is greater than or equal to the parameter value or not numeric.	less_than[8]
less_than_equal_to	Yes	Returns FALSE if the form element is greater than the parameter value, or not numeric.	less_than_equal_to[8]
alpha	No	Returns FALSE if the form element contains anything other than alphabetical characters.	
alpha_numeric	No	Returns FALSE if the form element contains anything other than alpha-numeric characters.	
alpha_numeric_spaces	No	Returns FALSE if the form element contains anything other than alpha-numeric characters or spaces. Should be used after trim to avoid spaces at the beginning or end.	
alpha_dash	No	Returns FALSE if the form element contains anything other than alpha-numeric characters, underscores or dashes.	
numeric	No	Returns FALSE if the form element contains anything other than numeric characters.	
integer	No	Returns FALSE if the form element contains anything other than an integer.	
decimal	No	Returns FALSE if the form element contains anything other than a decimal number.	
is_natural	No	Returns FALSE if the form element contains anything other than a natural number: 0, 1, 2, 3, etc.	
is_natural_no_zero	No	Returns FALSE if the form element contains anything other than a natural number, but not zero: 1, 2, 3, etc.	
valid_url	No	Returns FALSE if the form element does not contain a valid URL.	
valid_email	No	Returns FALSE if the form element does not contain a valid email address.	
valid_emails	No	Returns FALSE if any value provided in a comma separated list is not a valid email.	
valid_ip	No	Returns FALSE if the supplied IP is not valid. Accepts an optional parameter of 'ipv4' or 'ipv6' to specify an IP format.	
valid_base64	No	Returns FALSE if the supplied string contains anything other than valid Base64 characters.	

: These rules can also be called as discrete methods. For example:

```
$this->form_validation->required($string);
```

: You can also use any native PHP functions that permit up to two parameters, where at least one is required (to pass

the field data).

Prepping Reference

The following is a list of all the prepping methods that are available to use:

Name	Parameter	Description
xss_clean	No	Runs the data through the XSS filtering method, described in the <i>Security Class</i> page.
prep_for_form	No	Converts special characters so that HTML data can be shown in a form field without breaking it.
prep_url	No	Adds “http://” to URLs if missing.
strip_image_tags	No	Strips the HTML from image tags leaving the raw URL.
en-code_php_tags	No	Converts PHP tags to entities.

: You can also use any native PHP functions that permits one parameter, like `trim()`, `htmlspecialchars()`, `urldecode()`, etc.

Class Reference

class **Form_validation**

The following methods are intended for use in your controller.

`$this->form_validation->set_rules()`

```
Form_validation::set_rules($field, $label = '', $rules = '')
```

- **\$field** (*string*) – The field name
- **\$label** (*string*) – The field label
- **\$rules** (*mixed*) – The rules, as a string with rules separated by a pipe “|”, or an array or rules.

Object

Permits you to set validation rules, as described in the tutorial sections above:

- *Setting Validation Rules*
- *Saving Sets of Validation Rules to a Config File*

`$this->form_validation->run()`

```
Form_validation::run($group = '')
```

- **\$group** (*string*) – The name of the validation group to run

Boolean

Runs the validation routines. Returns boolean TRUE on success and FALSE on failure. You can optionally pass the name of the validation group via the method, as described in: *Saving Sets of Validation Rules to a Config File*

`$this->form_validation->set_message()`

```
Form_validation::set_message($lang, $val = '')
```

- **\$lang** (*string*) – The rule the message is for
- **\$val** (*string*) – The message

Object

Permits you to set custom error messages. See *Setting Error Messages*

`$this->form_validation->set_data()`

```
Form_validation::set_data($data = '')
```

- **\$data** (*array*) – The data to validate

Permits you to set an array for validation, instead of using the default \$_POST array.

`$this->form_validation->reset_validation()`

```
Form_validation::reset_validation()
```

Permits you to reset the validation when you validate more than one array. This method should be called before validating each new array.

`$this->form_validation->error_array()`

```
Form_validation::error_array()
```

Array

Returns the error messages as an array.

Helper Reference

The following helper functions are available for use in the view files containing your forms. Note that these are procedural functions, so they **do not** require you to prepend them with `$this->form_validation`.

`form_error()`

Shows an individual error message associated with the field name supplied to the function. Example:

```
<?php echo form_error('username'); ?>
```

The error delimiters can be optionally specified. See the *Changing the Error Delimiters* section above.

validation_errors()

Shows all error messages as a string: Example:

```
<?php echo validation_errors(); ?>
```

The error delimiters can be optionally specified. See the *Changing the Error Delimiters* section above.

set_value()

Permits you to set the value of an input form or textarea. You must supply the field name via the first parameter of the function. The second (optional) parameter allows you to set a default value for the form. Example:

```
<input type="text" name="quantity" value="<?php echo set_value('quantity', '0'); ?>" size="50" />
```

The above form will show “0” when loaded for the first time.

set_select()

If you use a <select> menu, this function permits you to display the menu item that was selected. The first parameter must contain the name of the select menu, the second parameter must contain the value of each item, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<select name="myselect">
<option value="one" <?php echo set_select('myselect', 'one', TRUE); ?> >One</option>
<option value="two" <?php echo set_select('myselect', 'two'); ?> >Two</option>
<option value="three" <?php echo set_select('myselect', 'three'); ?> >Three</option>
</select>
```

set_checkbox()

Permits you to display a checkbox in the state it was submitted. The first parameter must contain the name of the checkbox, the second parameter must contain its value, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE). Example:

```
<input type="checkbox" name="mycheck[]" value="1" <?php echo set_checkbox('mycheck[]', '1'); ?> />
<input type="checkbox" name="mycheck[]" value="2" <?php echo set_checkbox('mycheck[]', '2'); ?> />
```

set_radio()

Permits you to display radio buttons in the state they were submitted. This function is identical to the **set_checkbox()** function above.

```
<input type="radio" name="myradio" value="1" <?php echo set_radio('myradio', '1', TRUE); ?> />
<input type="radio" name="myradio" value="2" <?php echo set_radio('myradio', '2'); ?> />
```

10.13.10 FTP Class

CodeIgniter's FTP Class permits files to be transferred to a remote server. Remote files can also be moved, renamed, and deleted. The FTP class also includes a "mirroring" function that permits an entire local directory to be recreated remotely via FTP.

: SFTP and SSL FTP protocols are not supported, only standard FTP.

Initializing the Class

Like most other classes in CodeIgniter, the FTP class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('ftp');
```

Once loaded, the FTP object will be available using: `$this->ftp`

Usage Examples

In this example a connection is opened to the FTP server, and a local file is read and uploaded in ASCII mode. The file permissions are set to 755.

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$this->ftp->upload('/local/path/to/myfile.html', '/public_html/myfile.html', 'ascii', 0775);

$this->ftp->close();
```

In this example a list of files is retrieved from the server.

```
$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$list = $this->ftp->list_files('/public_html/');

print_r($list);

$this->ftp->close();
```

In this example a local directory is mirrored on the server.

```

$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['debug']    = TRUE;

$this->ftp->connect($config);

$this->ftp->mirror('/path/to/myfolder/', '/public_html/myfolder/');

$this->ftp->close();

```

Function Reference

\$this->ftp->connect()

Connects and logs into to the FTP server. Connection preferences are set by passing an array to the function, or you can store them in a config file.

Here is an example showing how you set preferences manually:

```

$this->load->library('ftp');

$config['hostname'] = 'ftp.example.com';
$config['username'] = 'your-username';
$config['password'] = 'your-password';
$config['port']     = 21;
$config['passive']  = FALSE;
$config['debug']    = TRUE;

$this->ftp->connect($config);

```

Setting FTP Preferences in a Config File If you prefer you can store your FTP preferences in a config file. Simply create a new file called the ftp.php, add the \$config array in that file. Then save the file at config/ftp.php and it will be used automatically.

Available connection options

- **hostname** - the FTP hostname. Usually something like: ftp.example.com
- **username** - the FTP username.
- **password** - the FTP password.
- **port** - The port number. Set to 21 by default.
- **debug** - TRUE/FALSE (boolean). Whether to enable debugging to display error messages.
- **passive** - TRUE/FALSE (boolean). Whether to use passive mode. Passive is set automatically by default.

\$this->ftp->upload()

Uploads a file to your server. You must supply the local path and the remote path, and you can optionally set the mode and permissions. Example:

```
$this->ftp->upload('/local/path/to/myfile.html', '/public_html/myfile.html', 'ascii', 0775);
```

Mode options are: ascii, binary, and auto (the default). If auto is used it will base the mode on the file extension of the source file.

If set, permissions have to be passed as an octal value.

\$this->ftp->download()

Downloads a file from your server. You must supply the remote path and the local path, and you can optionally set the mode. Example:

```
$this->ftp->download('/public_html/myfile.html', '/local/path/to/myfile.html', 'ascii');
```

Mode options are: ascii, binary, and auto (the default). If auto is used it will base the mode on the file extension of the source file.

Returns FALSE if the download does not execute successfully (including if PHP does not have permission to write the local file)

\$this->ftp->rename()

Permits you to rename a file. Supply the source file name/path and the new file name/path.

```
// Renames green.html to blue.html
$this->ftp->rename('/public_html/foo/green.html', '/public_html/foo/blue.html');
```

\$this->ftp->move()

Lets you move a file. Supply the source and destination paths:

```
// Moves blog.html from "joe" to "fred"
$this->ftp->move('/public_html/joe/blog.html', '/public_html/fred/blog.html');
```

Note: if the destination file name is different the file will be renamed.

\$this->ftp->delete_file()

Lets you delete a file. Supply the source path with the file name.

```
$this->ftp->delete_file('/public_html/joe/blog.html');
```

\$this->ftp->delete_dir()

Lets you delete a directory and everything it contains. Supply the source path to the directory with a trailing slash.

Important Be VERY careful with this function. It will recursively delete **everything** within the supplied path, including sub-folders and all files. Make absolutely sure your path is correct. Try using the `list_files()` function first to verify that your path is correct.

```
$this->ftp->delete_dir('/public_html/path/to/folder/');
```

`$this->ftp->list_files()`

Permits you to retrieve a list of files on your server returned as an array. You must supply the path to the desired directory.

```
$list = $this->ftp->list_files('/public_html/');

print_r($list);
```

`$this->ftp->mirror()`

Recursively reads a local folder and everything it contains (including sub-folders) and creates a mirror via FTP based on it. Whatever the directory structure of the original file path will be recreated on the server. You must supply a source path and a destination path:

```
$this->ftp->mirror('/path/to/myfolder/', '/public_html/myfolder/');
```

`$this->ftp->mkdir()`

Lets you create a directory on your server. Supply the path ending in the folder name you wish to create, with a trailing slash. Permissions can be set by passed an octal value in the second parameter (if you are running PHP 5).

```
// Creates a folder named "bar"
$this->ftp->mkdir('/public_html/foo/bar/', DIR_WRITE_MODE);
```

`$this->ftp->chmod()`

Permits you to set file permissions. Supply the path to the file or folder you wish to alter permissions on:

```
// Chmod "bar" to 777
$this->ftp->chmod('/public_html/foo/bar/', DIR_WRITE_MODE);
```

`$this->ftp->close();`

Closes the connection to your server. It's recommended that you use this when you are finished uploading.

10.13.11 Image Manipulation Class

CodeIgniter's Image Manipulation class lets you perform the following actions:

- Image Resizing
- Thumbnail Creation
- Image Cropping
- Image Rotating
- Image Watermarking

All three major image libraries are supported: GD/GD2, NetPBM, and ImageMagick

: Watermarking is only available using the GD/GD2 library. In addition, even though other libraries are supported, GD is required in order for the script to calculate the image properties. The image processing, however, will be performed with the library you specify.

Initializing the Class

Like most other classes in CodeIgniter, the image class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('image_lib');
```

Once the library is loaded it will be ready for use. The image library object you will use to call all functions is: `$this->image_lib`

Processing an Image

Regardless of the type of processing you would like to perform (resizing, cropping, rotation, or watermarking), the general process is identical. You will set some preferences corresponding to the action you intend to perform, then call one of four available processing functions. For example, to create an image thumbnail you'll do this:

```
$config['image_library'] = 'gd2';
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['create_thumb'] = TRUE;
$config['maintain_ratio'] = TRUE;
$config['width']         = 75;
$config['height']        = 50;
```

```
$this->load->library('image_lib', $config);
```

```
$this->image_lib->resize();
```

The above code tells the `image_resize` function to look for an image called *mypic.jpg* located in the `source_image` folder, then create a thumbnail that is 75 X 50 pixels using the GD2 `image_lib`. Since the `maintain_ratio` option is enabled, the thumb will be as close to the target width and height as possible while preserving the original aspect ratio. The thumbnail will be called *mypic_thumb.jpg*

: In order for the image class to be allowed to do any processing, the folder containing the image files must have write permissions.

: Image processing can require a considerable amount of server memory for some operations. If you are experiencing out of memory errors while processing images you may need to limit their maximum size, and/or adjust PHP memory limits.

Processing Functions

There are four available processing functions:

- `$this->image_lib->resize()`
- `$this->image_lib->crop()`

- `$this->image_lib->rotate()`
- `$this->image_lib->watermark()`
- `$this->image_lib->clear()`

These functions return boolean TRUE upon success and FALSE for failure. If they fail you can retrieve the error message using this function:

```
echo $this->image_lib->display_errors();
```

A good practice is use the processing function conditionally, showing an error upon failure, like this:

```
if ( ! $this->image_lib->resize() )
{
    echo $this->image_lib->display_errors();
}
```

: You can optionally specify the HTML formatting to be applied to the errors, by submitting the opening/closing tags in the function, like this:

```
$this->image_lib->display_errors(' <p>', ' </p>' );
```

Preferences

The preferences described below allow you to tailor the image processing to suit your needs.

Note that not all preferences are available for every function. For example, the x/y axis preferences are only available for image cropping. Likewise, the width and height preferences have no effect on cropping. The “availability” column indicates which functions support a given preference.

Availability Legend:

- R - Image Resizing
- C - Image Cropping
- X - Image Rotation
- W - Image Watermarking

Pref-er-ence	De-fault Value	Options	Description	Avail-ability
image_library	GD2	GD, GD2, ImageMagick, NetPBM	Sets the image library to be used.	R, C, X, W
library_path	None	None	Sets the server path to your ImageMagick or NetPBM library. If you use either of those libraries you must supply the path.	R, C, X R, C, S, W
source_image	None	None	Sets the source image name/path. The path must be a relative or absolute server path, not a URL.	
dynamic_output	FALSE	TRUE/FALSE (boolean)	Determines whether the new image file should be written to disk or generated dynamically. Note: If you choose the dynamic setting, only one image can be shown at a time, and it can't be positioned on the page. It simply outputs the raw image dynamically to your browser, along with image headers.	R, C, X, W
quality	90%	1 - 100%	Sets the quality of the image. The higher the quality the larger the file size.	R, C, X, W
new_image	None	None	Sets the destination image name/path. You'll use this preference when creating an image copy. The path must be a relative or absolute server path, not a URL.	R, C, X, W
width	None	None	Sets the width you would like the image set to.	R, C
height	None	None	Sets the height you would like the image set to.	R, C
create_thumb	FALSE	TRUE/FALSE (boolean)	Tells the image processing function to create a thumb.	R
thumb_marker	None	None	Specifies the thumbnail indicator. It will be inserted just before the file extension, so mypic.jpg would become mypic_thumb.jpg	R
maintain_ratio	TRUE	TRUE/FALSE (boolean)	Specifies whether to maintain the original aspect ratio when resizing or use hard values.	R, C
master_dim	auto	auto, width, height	Specifies what to use as the master axis when resizing or creating thumbs. For example, let's say you want to resize an image to 100 X 75 pixels. If the source image size does not allow perfect resizing to those dimensions, this setting determines which axis should be used as the hard value. "auto" sets the axis automatically based on whether the image is taller then wider, or vice versa.	R
rotation_angle	None	90, 180, 270, vrt, hor	Specifies the angle of rotation when rotating images. Note that PHP rotates counter-clockwise, so a 90 degree rotation to the right must be specified as 270.	X
x_axis	None	None	Sets the X coordinate in pixels for image cropping. For example, a setting of 30 will crop an image 30 pixels from the left.	C
y_axis	None	None	Sets the Y coordinate in pixels for image cropping. For example, a setting of 30 will crop an image 30 pixels from the top.	C

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called `image_lib.php`, add the `$config` array in that file. Then save the file in: `config/image_lib.php` and it will be used automatically. You will NOT need to use the `$this->image_lib->initialize` function if you save your preferences in a config file.

`$this->image_lib->resize()`

The image resizing function lets you resize the original image, create a copy (with or without resizing), or create a thumbnail image.

For practical purposes there is no difference between creating a copy and creating a thumbnail except a thumb will have the thumbnail marker as part of the name (ie, mypic_thumb.jpg).

All preferences listed in the table above are available for this function except these three: `rotation_angle`, `x_axis`, and `y_axis`.

Creating a Thumbnail The resizing function will create a thumbnail file (and preserve the original) if you set this preference to `TRUE`:

```
$config['create_thumb'] = TRUE;
```

This single preference determines whether a thumbnail is created or not.

Creating a Copy The resizing function will create a copy of the image file (and preserve the original) if you set a path and/or a new filename using this preference:

```
$config['new_image'] = '/path/to/new_image.jpg';
```

Notes regarding this preference:

- If only the new image name is specified it will be placed in the same folder as the original
- If only the path is specified, the new image will be placed in the destination with the same name as the original.
- If both the path and image name are specified it will be placed in its own destination and given the new name.

Resizing the Original Image If neither of the two preferences listed above (`create_thumb`, and `new_image`) are used, the resizing function will instead target the original image for processing.

`$this->image_lib->crop()`

The cropping function works nearly identically to the resizing function except it requires that you set preferences for the X and Y axis (in pixels) specifying where to crop, like this:

```
$config['x_axis'] = '100';
$config['y_axis'] = '40';
```

All preferences listed in the table above are available for this function except these: `rotation_angle`, `create_thumb`, `new_image`.

Here's an example showing how you might crop an image:

```

$config['image_library'] = 'imagemagick';
$config['library_path'] = '/usr/X11R6/bin/';
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['x_axis'] = '100';
$config['y_axis'] = '60';

$this->image_lib->initialize($config);

if ( ! $this->image_lib->crop() )

```

```
{
    echo $this->image_lib->display_errors();
}
```

: Without a visual interface it is difficult to crop images, so this function is not very useful unless you intend to build such an interface. That's exactly what we did using for the photo gallery module in ExpressionEngine, the CMS we develop. We added a JavaScript UI that lets the cropping area be selected.

`$this->image_lib->rotate()`

The image rotation function requires that the angle of rotation be set via its preference:

```
$config['rotation_angle'] = '90';
```

There are 5 rotation options:

1. 90 - rotates counter-clockwise by 90 degrees.
2. 180 - rotates counter-clockwise by 180 degrees.
3. 270 - rotates counter-clockwise by 270 degrees.
4. hor - flips the image horizontally.
5. vrt - flips the image vertically.

Here's an example showing how you might rotate an image:

```
$config['image_library'] = 'netpbm';
$config['library_path'] = '/usr/bin/';
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['rotation_angle'] = 'hor';

$this->image_lib->initialize($config);

if ( ! $this->image_lib->rotate() )
{
    echo $this->image_lib->display_errors();
}
```

`$this->image_lib->clear()`

The clear function resets all of the values used when processing an image. You will want to call this if you are processing images in a loop.

```
$this->image_lib->clear();
```

Image Watermarking

The Watermarking feature requires the GD/GD2 library.

Two Types of Watermarking

There are two types of watermarking that you can use:

- **Text:** The watermark message will be generating using text, either with a True Type font that you specify, or using the native text output that the GD library supports. If you use the True Type version your GD installation must be compiled with True Type support (most are, but not all).
- **Overlay:** The watermark message will be generated by overlaying an image (usually a transparent PNG or GIF) containing your watermark over the source image.

Watermarking an Image

Just as with the other functions (resizing, cropping, and rotating) the general process for watermarking involves setting the preferences corresponding to the action you intend to perform, then calling the watermark function. Here is an example:

```
$config['source_image'] = '/path/to/image/mypic.jpg';
$config['wm_text'] = 'Copyright 2006 - John Doe';
$config['wm_type'] = 'text';
$config['wm_font_path'] = './system/fonts/texb.ttf';
$config['wm_font_size'] = '16';
$config['wm_font_color'] = 'ffffff';
$config['wm_vrt_alignment'] = 'bottom';
$config['wm_hor_alignment'] = 'center';
$config['wm_padding'] = '20';

$this->image_lib->initialize($config);

$this->image_lib->watermark();
```

The above example will use a 16 pixel True Type font to create the text “Copyright 2006 - John Doe”. The watermark will be positioned at the bottom/center of the image, 20 pixels from the bottom of the image.

: In order for the image class to be allowed to do any processing, the image file must have “write” file permissions. For example, 777.

Watermarking Preferences

This table shown the preferences that are available for both types of watermarking (text or overlay)

Preference	Default Value	Options	Description
wm_type	text	text, overlay	Sets the type of watermarking that should be used.
source_image	None	None	Sets the source image name/path. The path must be a relative or absolute server path, not a URL.
dynamic_output	FALSE	TRUE/FALSE (boolean)	Determines whether the new image file should be written to disk or generated dynamically. Note: If you choose the dynamic setting, only one image can be shown at a time, and it can't be positioned on the page. It simply outputs the raw image dynamically to your browser, along with image headers.
quality	90%	1 - 100%	Sets the quality of the image. The higher the quality the larger the file size.
wm_padding	None	A number	The amount of padding, set in pixels, that will be applied to the watermark to set it away from the edge of your images.
wm_vrt_alignment	top	top, middle, bottom	Sets the vertical alignment for the watermark image.
wm_hor_alignment	center	left, center, right	Sets the horizontal alignment for the watermark image.
wm_hor_offset	None	None	You may specify a horizontal offset (in pixels) to apply to the watermark position. The offset normally moves the watermark to the right, except if you have your alignment set to "right" then your offset value will move the watermark toward the left of the image.
wm_vrt_offset	None	None	You may specify a vertical offset (in pixels) to apply to the watermark position. The offset normally moves the watermark down, except if you have your alignment set to "bottom" then your offset value will move the watermark toward the top of the image.

Text Preferences This table shown the preferences that are available for the text type of watermarking.

Preference	Default Value	Options	Description
wm_text	None	None	The text you would like shown as the watermark. Typically this will be a copyright notice.
wm_font_path	None	None	The server path to the True Type Font you would like to use. If you do not use this option, the native GD font will be used.
wm_font_size	16	None	The size of the text. Note: If you are not using the True Type option above, the number is set using a range of 1 - 5. Otherwise, you can use any valid pixel size for the font you're using.
wm_font_color	ffffff	None	The font color, specified in hex. Both the full 6-length (ie, 993300) and the short three character abbreviated version (ie, fff) are supported.
wm_shadow_color	None	None	The color of the drop shadow, specified in hex. If you leave this blank a drop shadow will not be used. Both the full 6-length (ie, 993300) and the short three character abbreviated version (ie, fff) are supported.
wm_shadow_distance	None	None	The distance (in pixels) from the font that the drop shadow should appear.

Overlay Preferences This table shown the preferences that are available for the overlay type of watermarking.

Preference	Default Value	Options	Description
wm_overlay	None	None	The server path to the image you wish to use as your watermark. Required only if you are using the overlay method.
wm_opacity	50	1 - 100	Image opacity. You may specify the opacity (i.e. transparency) of your watermark image. This allows the watermark to be faint and not completely obscure the details from the original image behind it. A 50% opacity is typical.
wm_x_transp		A number	If your watermark image is a PNG or GIF image, you may specify a color on the image to be “transparent”. This setting (along with the next) will allow you to specify that color. This works by specifying the “X” and “Y” coordinate pixel (measured from the upper left) within the image that corresponds to a pixel representative of the color you want to be transparent.
wm_y_transp		A number	Along with the previous setting, this allows you to specify the coordinate to a pixel representative of the color you want to be transparent.

10.13.12 Input Class

The Input Class serves two purposes:

1. It pre-processes global input data for security.
2. It provides some helper methods for fetching input data and pre-processing it.

: This class is initialized automatically by the system so there is no need to do it manually.

Security Filtering

The security filtering method is called automatically when a new *controller* is invoked. It does the following:

- If `$config['allow_get_array']` is FALSE (default is TRUE), destroys the global GET array.
- Destroys all global variables in the event `register_globals` is turned on.
- Filters the GET/POST/COOKIE array keys, permitting only alpha-numeric (and a few other) characters.
- Provides XSS (Cross-site Scripting Hacks) filtering. This can be enabled globally, or upon request.
- Standardizes newline characters to `\n` (In Windows `\r\n`)

XSS Filtering

The Input class has the ability to filter input automatically to prevent cross-site scripting attacks. If you want the filter to run automatically every time it encounters POST or COOKIE data you can enable it by opening your application/config/config.php file and setting this:

```
$config['global_xss_filtering'] = TRUE;
```

Please refer to the *Security class* documentation for information on using XSS Filtering in your application.

Using POST, GET, COOKIE, or SERVER Data

CodeIgniter comes with four helper methods that let you fetch POST, GET, COOKIE or SERVER items. The main advantage of using the provided methods rather than fetching an item directly (`$_POST['something']`) is that

the methods will check to see if the item is set and return NULL if not. This lets you conveniently use data without having to test whether an item exists first. In other words, normally you might do something like this:

```
$something = isset($_POST['something']) ? $_POST['something'] : NULL;
```

With CodeIgniter's built in methods you can simply do this:

```
$something = $this->input->post('something');
```

The four methods are:

- `$this->input->post()`
- `$this->input->get()`
- `$this->input->cookie()`
- `$this->input->server()`

`$this->input->post()`

The first parameter will contain the name of the POST item you are looking for:

```
$this->input->post('some_data');
```

The method returns NULL if the item you are attempting to retrieve does not exist.

The second optional parameter lets you run the data through the XSS filter. It's enabled by setting the second parameter to boolean TRUE;

```
$this->input->post('some_data', TRUE);
```

To return an array of all POST items call without any parameters.

To return all POST items and pass them through the XSS filter set the first parameter NULL while setting the second parameter to boolean;

The method returns NULL if there are no items in the POST.

```
$this->input->post(NULL, TRUE); // returns all POST items with XSS filter  
$this->input->post(); // returns all POST items without XSS filter
```

`$this->input->get()`

This method is identical to the POST method, only it fetches GET data

```
$this->input->get('some_data', TRUE);
```

To return an array of all GET items call without any parameters.

To return all GET items and pass them through the XSS filter set the first parameter NULL while setting the second parameter to boolean;

The method returns NULL if there are no items in the GET.

```
$this->input->get(NULL, TRUE); // returns all GET items with XSS filter  
$this->input->get(); // returns all GET items without XSS filtering
```

`$this->input->post_get()`

This method will search through both the POST and GET streams for data, looking first in POST, and then in GET:

```
$this->input->post_get('some_data', TRUE);
```

`$this->input->get_post()`

This method will search through both the POST and GET streams for data, looking first in GET, and then in POST:

```
$this->input->get_post('some_data', TRUE);
```

`$this->input->cookie()`

This method is identical to the POST method, only it fetches cookie data

```
$this->input->cookie('some_cookie');  
$this->input->cookie('some_cookie', TRUE); // with XSS filter
```

`$this->input->server()`

This method is identical to the above methods, only it fetches server data:

```
$this->input->server('some_data');
```

Using the `php://input` stream

If you want to utilize the PUT, DELETE, PATCH or other exotic request methods, they can only be accessed via a special input stream, that can only be read once. This isn't as easy as just reading from e.g. the `$_POST` array, because it will always exist and you can try and access multiple variables without caring that you might only have one shot at all of the POST data.

CodeIgniter will take care of that for you, and you can access data from the **`php://input`** stream at any time, just by calling the `input_stream()` method:

```
$this->input->input_stream('key');
```

Similar to the methods above, if the requested data is not found, it will return NULL and you can also decide whether to run the data through `xss_clean()` by passing a boolean value as the second parameter:

```
$this->input->input_stream('key', TRUE); // XSS Clean  
$this->input->input_stream('key', FALSE); // No XSS filter
```

: You can utilize `method()` in order to know if you're reading PUT, DELETE or PATCH data.

`$this->input->set_cookie()`

Sets a cookie containing the values you specify. There are two ways to pass information to this method so that a cookie can be set: Array Method, and Discrete Parameters:

Array Method

Using this method, an associative array is passed to the first parameter:

```
$cookie = array(
    'name'    => 'The Cookie Name',
    'value'   => 'The Value',
    'expire'  => '86500',
    'domain'  => '.some-domain.com',
    'path'    => '/',
    'prefix'  => 'myprefix_',
    'secure'  => TRUE
);

$this->input->set_cookie($cookie);
```

Notes:

Only the name and value are required. To delete a cookie set it with the expiration blank.

The expiration is set in **seconds**, which will be added to the current time. Do not include the time, but rather only the number of seconds from *now* that you wish the cookie to be valid. If the expiration is set to zero the cookie will only last as long as the browser is open.

For site-wide cookies regardless of how your site is requested, add your URL to the **domain** starting with a period, like this: `.your-domain.com`

The path is usually not needed since the method sets a root path.

The prefix is only needed if you need to avoid name collisions with other identically named cookies for your server.

The secure boolean is only needed if you want to make it a secure cookie by setting it to TRUE.

Discrete Parameters

If you prefer, you can set the cookie by passing data using individual parameters:

```
$this->input->set_cookie($name, $value, $expire, $domain, $path, $prefix, $secure);
```

\$this->input->ip_address()

Returns the IP address for the current user. If the IP address is not valid, the method will return an IP of: 0.0.0.0

```
echo $this->input->ip_address();
```

\$this->input->valid_ip(\$ip)

Takes an IP address as input and returns TRUE or FALSE (boolean) if it is valid or not.

: The `$this->input->ip_address()` method above automatically validates the IP address.

```
if ( ! $this->input->valid_ip($ip) )
{
    echo 'Not Valid';
}
else
```

```
{
    echo 'Valid';
}
```

Accepts an optional second string parameter of 'ipv4' or 'ipv6' to specify an IP format. The default checks for both formats.

`$this->input->user_agent()`

Returns the user agent (web browser) being used by the current user. Returns FALSE if it's not available.

```
echo $this->input->user_agent();
```

See the *User Agent Class* for methods which extract information from the user agent string.

`$this->input->request_headers()`

Useful if running in a non-Apache environment where `apache_request_headers()` will not be supported. Returns an array of headers.

```
$headers = $this->input->request_headers();
```

`$this->input->get_request_header()`

Returns a single member of the request headers array.

```
$this->input->get_request_header('some-header', TRUE);
```

`$this->input->is_ajax_request()`

Checks to see if the HTTP_X_REQUESTED_WITH server header has been set, and returns a boolean response.

`$this->input->is_cli_request()`

Checks to see if the STDIN constant is set, which is a failsafe way to see if PHP is being run on the command line.

```
$this->input->is_cli_request();
```

: This method is DEPRECATED and is now just an alias for the `is_cli()` function.

`$this->input->method()`

Returns the `$_SERVER['REQUEST_METHOD']`, optional set uppercase or lowercase (default lowercase).

```
echo $this->input->method(TRUE); // Outputs: POST
echo $this->input->method(FALSE); // Outputs: post
echo $this->input->method(); // Outputs: post
```

: This driver is experimental. Its feature set and implementation may change in future releases.

10.13.13 Javascript Class

CodeIgniter provides a library to help you with certain common functions that you may want to use with Javascript. Please note that CodeIgniter does not require the jQuery library to run, and that any scripting library will work equally well. The jQuery library is simply presented as a convenience if you choose to use it.

Initializing the Class

To initialize the Javascript class manually in your controller constructor, use the `$this->load->library` function. Currently, the only available library is jQuery, which will automatically be loaded like this:

```
$this->load->library('javascript');
```

The Javascript class also accepts parameters, `js_library_driver` (string) default 'jquery' and `autoload` (bool) default TRUE. You may override the defaults if you wish by sending an associative array:

```
$this->load->library('javascript', array('js_library_driver' => 'scripto', 'autoload' => FALSE));
```

Again, presently only 'jquery' is available. You may wish to set `autoload` to FALSE, though, if you do not want the jQuery library to automatically include a script tag for the main jQuery script file. This is useful if you are loading it from a location outside of CodeIgniter, or already have the script tag in your markup.

Once loaded, the jQuery library object will be available using: `$this->javascript`

Setup and Configuration

Set these variables in your view

As a Javascript library, your files must be available to your application.

As Javascript is a client side language, the library must be able to write content into your final output. This generally means a view. You'll need to include the following variables in the `<head>` sections of your output.

```
<?php echo $library_src;?>
<?php echo $script_head;?>
```

`$library_src`, is where the actual library file will be loaded, as well as any subsequent plugin script calls; `$script_head` is where specific events, functions and other commands will be rendered.

Set the path to the libraries with config items

There are some configuration items in Javascript library. These can either be set in `application/config.php`, within its own `config/javascript.php` file, or within any controller using the `set_item()` function.

An image to be used as an "ajax loader", or progress indicator. Without one, the simple text message of "loading" will appear when Ajax calls need to be made.

```
$config['javascript_location'] = 'http://localhost/codeigniter/themes/js/jquery/';
$config['javascript_ajax_img'] = 'images/ajax-loader.gif';
```

If you keep your files in the same directories they were downloaded from, then you need not set this configuration items.

The jQuery Class

To initialize the jQuery class manually in your controller constructor, use the `$this->load->library` function:

```
$this->load->library('javascript/jquery');
```

You may send an optional parameter to determine whether or not a script tag for the main jQuery file will be automatically included when loading the library. It will be created by default. To prevent this, load the library as follows:

```
$this->load->library('javascript/jquery', FALSE);
```

Once loaded, the jQuery library object will be available using: `$this->jquery`

jQuery Events

Events are set using the following syntax.

```
$this->jquery->event('element_path', code_to_run());
```

In the above example:

- “event” is any of blur, change, click, dblclick, error, focus, hover, keydown, keyup, load, mousedown, mouseup, mouseover, mouseup, resize, scroll, or unload.
- “element_path” is any valid [jQuery selector](#). Due to jQuery’s unique selector syntax, this is usually an element id, or CSS selector. For example “#notice_area” would effect `<div id=“notice_area”>`, and “#content a.notice” would effect all anchors with a class of “notice” in the div with id “content”.
- “code_to_run()” is script your write yourself, or an action such as an effect from the jQuery library below.

Effects

The query library supports a powerful [Effects](#) repertoire. Before an effect can be used, it must be loaded:

```
$this->jquery->effect([optional path] plugin name); // for example $this->jquery->effect('bounce');
```

hide() / show()

Each of this functions will affect the visibility of an item on your page. `hide()` will set an item invisible, `show()` will reveal it.

```
$this->jquery->hide(target, optional speed, optional extra information);
$this->jquery->show(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

toggle()

`toggle()` will change the visibility of an item to the opposite of its current state, hiding visible elements, and revealing hidden ones.

```
$this->jquery->toggle(target);
```

- “target” will be any valid jQuery selector or selectors.

animate()

```
$this->jquery->animate(target, parameters, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “parameters” in jQuery would generally include a series of CSS properties that you wish to change.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

For a full summary, see <http://docs.jquery.com/Effects/animate>

Here is an example of an `animate()` called on a div with an id of “note”, and triggered by a click using the jQuery library’s `click()` event.

```
$params = array(
    'height' => 80,
    'width' => '50%',
    'marginLeft' => 125
);
$this->jquery->click('#trigger', $this->jquery->animate('#note', $params, 'normal'));
```

fadeIn() / fadeOut()

```
$this->jquery->fadeIn(target, optional speed, optional extra information);
$this->jquery->fadeOut(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

toggleClass()

This function will add or remove a CSS class to its target.

```
$this->jquery->toggleClass(target, class)
```

- “target” will be any valid jQuery selector or selectors.
- “class” is any CSS classname. Note that this class must be defined and available in a CSS that is already loaded.

fadeIn() / fadeOut()

These effects cause an element(s) to disappear or reappear over time.

```
$this->jquery->fadeIn(target, optional speed, optional extra information);
$this->jquery->fadeOut(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

slideUp() / slideDown() / slideToggle()

These effects cause an element(s) to slide.

```
$this->jquery->slideUp(target, optional speed, optional extra information);
$this->jquery->slideDown(target, optional speed, optional extra information);
$this->jquery->slideToggle(target, optional speed, optional extra information);
```

- “target” will be any valid jQuery selector or selectors.
- “speed” is optional, and is set to either slow, normal, fast, or alternatively a number of milliseconds.
- “extra information” is optional, and could include a callback, or other additional information.

Plugins

Some select jQuery plugins are made available using this library.

corner()

Used to add distinct corners to page elements. For full details see <http://www.malsup.com/jquery/corner/>

```
$this->jquery->corner(target, corner_style);
```

- “target” will be any valid jQuery selector or selectors.
- “corner_style” is optional, and can be set to any valid style such as round, sharp, bevel, bite, dog, etc. Individual corners can be set by following the style with a space and using “tl” (top left), “tr” (top right), “bl” (bottom left), or “br” (bottom right).

```
$this->jquery->corner("#note", "cool tl br");
```

10.13.14 Language Class

The Language Class provides functions to retrieve language files and lines of text for purposes of internationalization.

In your CodeIgniter system folder you'll find one called `language` containing sets of language files. You can create your own language files as needed in order to display error and other messages in other languages.

Language files are typically stored in your **system/language/** directory. Alternately you can create a directory called `language` inside your application folder and store them there. CodeIgniter will always load the one in **system/language/** first and will then look for an override in your **application/language/** directory.

: Each language should be stored in its own folder. For example, the English files are located at: `system/language/english`

Creating Language Files

Language files must be named with **_lang.php** as the file extension. For example, let's say you want to create a file containing error messages. You might name it: `error_lang.php`

Within the file you will assign each line of text to an array called `$lang` with this prototype:

```
$lang['language_key'] = 'The actual message to be shown';
```

: It's a good practice to use a common prefix for all messages in a given file to avoid collisions with similarly named items in other files. For example, if you are creating error messages you might prefix them with `error_`

```
$lang['error_email_missing'] = 'You must submit an email address';  
$lang['error_url_missing'] = 'You must submit a URL';  
$lang['error_username_missing'] = 'You must submit a username';
```

Loading A Language File

In order to fetch a line from a particular file you must load the file first. Loading a language file is done with the following code:

```
$this->lang->load('filename', 'language');
```

Where `filename` is the name of the file you wish to load (without the file extension), and `language` is the language set containing it (ie, english). If the second parameter is missing, the default language set in your **application/config/config.php** file will be used.

: The *language* parameter can only consist of letters.

Fetching a Line of Text

Once your desired language file is loaded you can access any line of text using this function:

```
$this->lang->line('language_key');
```

Where *language_key* is the array key corresponding to the line you wish to show.

You can optionally pass `FALSE` as the second argument of that method to disable error logging, in case you're not sure if the line exists:

```
$this->lang->line('misc_key', FALSE);
```

: This method simply returns the line. It does not echo it.

Using language lines as form labels

This feature has been deprecated from the language library and moved to the `lang()` function of the *Language Helper*.

Auto-loading Languages

If you find that you need a particular language globally throughout your application, you can tell CodeIgniter to *auto-load* it during system initialization. This is done by opening the **application/config/autoload.php** file and adding the language(s) to the autoload array.

10.13.15 Loader Class

Loader, as the name suggests, is used to load elements. These elements can be libraries (classes) *View files*, *Drivers*, *Helpers*, *Models*, or your own files.

: This class is initialized automatically by the system so there is no need to do it manually.

The following methods are available in this class:

`$this->load->library('class_name', $config, 'object name')`

This method is used to load core classes. Where `class_name` is the name of the class you want to load.

: We use the terms “class” and “library” interchangeably.

For example, if you would like to send email with CodeIgniter, the first step is to load the email class within your controller:

```
$this->load->library('email');
```

Once loaded, the library will be ready for use, using `$this->email->*some_method*()`.

Library files can be stored in subdirectories within the main “libraries” directory, or within your personal application/libraries directory. To load a file located in a subdirectory, simply include the path, relative to the “libraries” directory. For example, if you have file located at:

```
libraries/flavors/Chocolate.php
```

You will load it using:

```
$this->load->library('flavors/chocolate');
```

You may nest the file in as many subdirectories as you want.

Additionally, multiple libraries can be loaded at the same time by passing an array of libraries to the load method.

```
$this->load->library(array('email', 'table'));
```

Setting options

The second (optional) parameter allows you to optionally pass configuration setting. You will typically pass these as an array:

```
$config = array (
    'mailtype' => 'html',
    'charset'  => 'utf-8',
    'priority' => '1'
);

$this->load->library('email', $config);
```

Config options can usually also be set via a config file. Each library is explained in detail in its own page, so please read the information regarding each one you would like to use.

Please take note, when multiple libraries are supplied in an array for the first parameter, each will receive the same parameter information.

Assigning a Library to a different object name

If the third (optional) parameter is blank, the library will usually be assigned to an object with the same name as the library. For example, if the library is named Calendar, it will be assigned to a variable named `$this->calendar`.

If you prefer to set your own class names you can pass its value to the third parameter:

```
$this->load->library('calendar', '', 'my_calendar');

// Calendar class is now accessed using:
$this->my_calendar
```

Please take note, when multiple libraries are supplied in an array for the first parameter, this parameter is discarded.

`$this->load->driver('parent_name', $config, 'object name')`

This method is used to load driver libraries. Where `parent_name` is the name of the parent class you want to load.

As an example, if you would like to use sessions with CodeIgniter, the first step is to load the session driver within your controller:

```
$this->load->driver('session');
```

Once loaded, the library will be ready for use, using `$this->session->*some_method*()`.

Driver files must be stored in a subdirectory within the main “libraries” directory, or within your personal application/libraries directory. The subdirectory must match the parent class name. Read the *Drivers* description for details.

Additionally, multiple driver libraries can be loaded at the same time by passing an array of drivers to the load method.

```
$this->load->driver(array('session', 'cache'));
```

Setting options

The second (optional) parameter allows you to optionally pass configuration settings. You will typically pass these as an array:

```
$config = array(
    'sess_driver' => 'cookie',
    'sess_encrypt_cookie' => true,
    'encryption_key' => 'mysecretkey'
);

$this->load->driver('session', $config);
```

Config options can usually also be set via a config file. Each library is explained in detail in its own page, so please read the information regarding each one you would like to use.

Assigning a Driver to a different object name

If the third (optional) parameter is blank, the library will be assigned to an object with the same name as the parent class. For example, if the library is named Session, it will be assigned to a variable named `$this->session`.

If you prefer to set your own class names you can pass its value to the third parameter:

```
$this->load->library('session', '', 'my_session');

// Session class is now accessed using:
$this->my_session
```

: Driver libraries may also be loaded with the `library()` method, but it is faster to use `driver()`.

`$this->load->view('file_name', $data, TRUE/FALSE)`

This method is used to load your View files. If you haven't read the *Views* section of the user guide it is recommended that you do since it shows you how this method is typically used.

The first parameter is required. It is the name of the view file you would like to load.

: The `.php` file extension does not need to be specified unless you use something other than `.php`.

The second **optional** parameter can take an associative array or an object as input, which it runs through the PHP `extract()` function to convert to variables that can be used in your view files. Again, read the *Views* page to learn how this might be useful.

The third **optional** parameter lets you change the behavior of the method so that it returns data as a string rather than sending it to your browser. This can be useful if you want to process the data in some way. If you set the parameter to `true` (boolean) it will return data. The default behavior is `false`, which sends it to your browser. Remember to assign it to a variable if you want the data returned:

```
$string = $this->load->view('myfile', '', true);
```

`$this->load->model('model_name');`

```
$this->load->model('model_name');
```

If your model is located in a subdirectory, include the relative path from your models directory. For example, if you have a model located at `application/models/blog/Queries.php` you'll load it using:

```
$this->load->model('blog/queries');
```

If you would like your model assigned to a different object name you can specify it via the second parameter of the loading method:

```
$this->load->model('model_name', 'fubar');  
$this->fubar->method();
```

`$this->load->database('options', TRUE/FALSE)`

This method lets you load the database class. The two parameters are **optional**. Please see the *database* section for more info.

`$this->load->vars($array)`

This method takes an associative array as input and generates variables using the PHP `extract` method. This method produces the same result as using the second parameter of the `$this->load->view()` method above. The reason you might want to use this method independently is if you would like to set some global variables in the constructor of your controller and have them become available in any view file loaded from any method. You can have multiple calls to this method. The data gets cached and merged into one array for conversion to variables.

`$this->load->get_var($key)`

This method checks the associative array of variables available to your views. This is useful if for any reason a var is set in a library or another controller method using `$this->load->vars()`.

`$this->load->get_vars()`

This method retrieves all variables available to your views.

`$this->load->clear_vars()`

Clears cached view variables.

`$this->load->helper('file_name')`

This method loads helper files, where `file_name` is the name of the file, without the `_helper.php` extension.

`$this->load->file('filepath/filename', TRUE/FALSE)`

This is a generic file loading method. Supply the filepath and name in the first parameter and it will open and read the file. By default the data is sent to your browser, just like a View file, but if you set the second parameter to true (boolean) it will instead return the data as a string.

`$this->load->language('file_name')`

This method is an alias of the *language loading method*: `$this->lang->load()`

`$this->load->config('file_name')`

This method is an alias of the *config file loading method*: `$this->config->load()`

`$this->load->is_loaded('library_name')`

The `is_loaded()` method allows you to check if a class has already been loaded or not.

: The word “class” here refers to libraries and drivers.

If the requested class has been loaded, the method returns its assigned name in the CI Super-object and FALSE if it's not:

```
$this->load->library('form_validation');
$this->load->is_loaded('Form_validation'); // returns 'form_validation'

$this->load->is_loaded('Nonexistent_library'); // returns FALSE
```

: If you have more than one instance of a class (assigned to different properties), then the first one will be returned.

```
$this->load->library('form_validation', $config, 'fv');
$this->load->library('form_validation');

$this->load->is_loaded('Form_validation'); // returns 'fv'
```

Application “Packages”

An application package allows for the easy distribution of complete sets of resources in a single directory, complete with its own libraries, models, helpers, config, and language files. It is recommended that these packages be placed in the `application/third_party` directory. Below is a sample map of an package directory

Sample Package “Foo Bar” Directory Map

The following is an example of a directory for an application package named “Foo Bar”.

```
/application/third_party/foo_bar

config/
helpers/
language/
libraries/
models/
```

Whatever the purpose of the “Foo Bar” application package, it has its own config files, helpers, language files, libraries, and models. To use these resources in your controllers, you first need to tell the Loader that you are going to be loading resources from a package, by adding the package path.

`$this->load->add_package_path()`

Adding a package path instructs the Loader class to prepend a given path for subsequent requests for resources. As an example, the “Foo Bar” application package above has a library named `Foo_bar.php`. In our controller, we’d do the following:

```
$this->load->add_package_path(APPPATH.'third_party/foo_bar/');
$this->load->library('foo_bar');
```

`$this->load->remove_package_path()`

When your controller is finished using resources from an application package, and particularly if you have other application packages you want to work with, you may wish to remove the package path so the Loader no longer looks in that directory for resources. To remove the last path added, simply call the method with no parameters.

`$this->load->remove_package_path()`

Or to remove a specific package path, specify the same path previously given to `add_package_path()` for a package.:

```
$this->load->remove_package_path(APPPATH.'third_party/foo_bar/');
```

Package view files

By Default, package view files paths are set when `add_package_path()` is called. View paths are looped through, and once a match is encountered that view is loaded.

In this instance, it is possible for view naming collisions within packages to occur, and possibly the incorrect package being loaded. To ensure against this, set an optional second parameter of `FALSE` when calling `add_package_path()`.

```
$this->load->add_package_path(APPPATH.'my_app', FALSE);
$this->load->view('my_app_index'); // Loads
$this->load->view('welcome_message'); // Will not load the default welcome_message b/c the second pa

// Reset things
$this->load->remove_package_path(APPPATH.'my_app');

// Again without the second parameter:
$this->load->add_package_path(APPPATH.'my_app');
$this->load->view('my_app_index'); // Loads
$this->load->view('welcome_message'); // Loads
```

10.13.16 Migrations Class

Migrations are a convenient way for you to alter your database in a structured and organized manner. You could edit fragments of SQL by hand but you would then be responsible for telling other developers that they need to go and run them. You would also have to keep track of which changes need to be run against the production machines next time you deploy.

The database table **migration** tracks which migrations have already been run so all you have to do is update your application files and call `$this->migration->current()` to work out which migrations should be run. The current version is found in `config/migration.php`.

Migration file names

Each Migration is run in numeric order forward or backwards depending on the method taken. Two numbering styles are available:

- **Sequential:** each migration is numbered in sequence, starting with **001**. Each number must be three digits, and there must not be any gaps in the sequence. (This was the numbering scheme prior to CodeIgniter 3.0.)
- **Timestamp:** each migration is numbered using the timestamp when the migration was created, in **YYYYM-MDDHHIIS** format (e.g. **20121031100537**). This helps prevent numbering conflicts when working in a team environment, and is the preferred scheme in CodeIgniter 3.0 and later.

The desired style may be selected using the `$config['migration_type']` setting in your **migration.php** config file.

Regardless of which numbering style you choose to use, prefix your migration files with the migration number followed by an underscore and a descriptive name for the migration. For example:

- **001_add_blog.php** (sequential numbering)
- **20121031100537_add_blog.php** (timestamp numbering)

Create a Migration

This will be the first migration for a new site which has a blog. All migrations go in the folder **application/migrations/** and have names such as **20121031100537_add_blog.php**:

```
<?php

defined('BASEPATH') OR exit('No direct script access allowed');

class Migration_Add_blog extends CI_Migration {

    public function up()
    {
        $this->dbforge->add_field(array(
            'blog_id' => array(
                'type' => 'INT',
                'constraint' => 5,
                'unsigned' => TRUE,
                'auto_increment' => TRUE
            ),
            'blog_title' => array(
                'type' => 'VARCHAR',
                'constraint' => '100',
            ),
            'blog_description' => array(
                'type' => 'TEXT',
                'null' => TRUE,
            ),
        ));
        $this->dbforge->add_key('blog_id', TRUE);
        $this->dbforge->create_table('blog');
    }

    public function down()
    {
        $this->dbforge->drop_table('blog');
    }
}
```

Then in **application/config/migration.php** set `$config['migration_version'] = 1;`.

Usage Example

In this example some simple code is placed in **application/controllers/Migrate.php** to update the schema.:

```
<?php

class Migrate extends CI_Controller
{
    public function index()
    {
        $this->load->library('migration');

        if ($this->migration->current() === FALSE)
        {
            show_error($this->migration->error_string());
        }
    }
}
```

Function Reference

`$this->migration->current()`

The current migration is whatever is set for `$config['migration_version']` in **application/config/migration.php**.

`$this->migration->error_string()`

This returns a string of errors while performing a migration.

`$this->migration->find_migrations()`

An array of migration filenames are returned that are found in the **migration_path** property.

`$this->migration->latest()`

This works much the same way as `current()` but instead of looking for the `$config['migration_version']` the Migration class will use the very newest migration found in the filesystem.

`$this->migration->version()`

Version can be used to roll back changes or step forwards programmatically to specific versions. It works just like `current` but ignores `$config['migration_version']`.:

```
$this->load->library('migration');
```

```
$this->migration->version(5);
```

Migration Preferences

The following is a table of all the config options for migrations.

Preference	Default	Options	Description
migration_enabled	FALSE	TRUE / FALSE	Enable or disable migrations.
migration_path	APP-PATH.'migrations/'	None	The path to your migrations folder.
migration_version	0	None	The current version your database should use.
migration_table	migrations	None	The table name for storing the schema version number.
migration_auto_latest	FALSE	TRUE / FALSE	Enable or disable automatically running migrations.
migration_type	'timestamp'	'timestamp' / 'sequential'	The type of numeric identifier used to name migration files.

10.13.17 Output Class

The Output class is a small class with one main function: To send the finalized web page to the requesting browser. It is also responsible for *caching* your web pages, if you use that feature.

: This class is initialized automatically by the system so there is no need to do it manually.

Under normal circumstances you won't even notice the Output class since it works transparently without your intervention. For example, when you use the *Loader* class to load a view file, it's automatically passed to the Output class, which will be called automatically by CodeIgniter at the end of system execution. It is possible, however, for you to manually intervene with the output if you need to, using either of the two following functions:

`$this->output->set_output();`

Permits you to manually set the final output string. Usage example:

```
$this->output->set_output($data);
```

: If you do set your output manually, it must be the last thing done in the function you call it from. For example, if you build a page in one of your controller functions, don't set the output until the end.

`$this->output->set_content_type();`

Permits you to set the mime-type of your page so you can serve JSON data, JPEG's, XML, etc easily.

```
$this->output
    ->set_content_type('application/json')
    ->set_output(json_encode(array('foo' => 'bar')));
```

```
$this->output
    ->set_content_type('jpeg') // You could also use ".jpeg" which will have the full stop removed by
    ->set_output(file_get_contents('files/something.jpg'));
```

: Make sure any non-mime string you pass to this method exists in config/mimes.php or it will have no effect.

You can also set the character set of the document, by passing a second argument:

```
$this->output->set_content_type('css', 'utf-8');
```

`$this->output->get_content_type()`

Returns the Content-Type HTTP header that's currently in use, excluding the character set value.

```
$mime = $this->output->get_content_type();
```

: If not set, the default return value is 'text/html'.

`$this->output->get_header()`

Gets the requested HTTP header value, if set.

If the header is not set, NULL will be returned. If an empty value is passed to the method, it will return FALSE.

Example:

```
$this->output->set_content_type('text/plain', 'UTF-8');  
echo $this->output->get_header('content-type');  
// Outputs: text/plain; charset=utf-8
```

: The header name is compared in a case-insensitive manner.

: Raw headers sent via PHP's native `header()` function are also detected.

`$this->output->get_output()`

Permits you to manually retrieve any output that has been sent for storage in the output class. Usage example:

```
$string = $this->output->get_output();
```

Note that data will only be retrievable from this function if it has been previously sent to the output class by one of the CodeIgniter functions like `$this->load->view()`.

`$this->output->append_output();`

Appends data onto the output string. Usage example:

```
$this->output->append_output($data);
```

`$this->output->set_header();`

Permits you to manually set server headers, which the output class will send for you when outputting the final rendered display. Example:

```
$this->output->set_header("HTTP/1.0 200 OK");
$this->output->set_header("HTTP/1.1 200 OK");
$this->output->set_header('Last-Modified: '.gmdate('D, d M Y H:i:s', $last_update).' GMT');
$this->output->set_header("Cache-Control: no-store, no-cache, must-revalidate");
$this->output->set_header("Cache-Control: post-check=0, pre-check=0");
$this->output->set_header("Pragma: no-cache");
```

`$this->output->set_status_header(code, 'text');`

Permits you to manually set a server status header. Example:

```
$this->output->set_status_header('401');
// Sets the header as: Unauthorized
```

See [here](#) for a full list of headers.

: This method is an alias for *Common function* `set_status_header()`.

`$this->output->enable_profiler();`

Permits you to enable/disable the *Profiler*, which will display benchmark and other data at the bottom of your pages for debugging and optimization purposes.

To enable the profiler place the following function anywhere within your *Controller* functions:

```
$this->output->enable_profiler(TRUE);
```

When enabled a report will be generated and inserted at the bottom of your pages.

To disable the profiler you will use:

```
$this->output->enable_profiler(FALSE);
```

`$this->output->set_profiler_sections();`

Permits you to enable/disable specific sections of the Profiler when enabled. Please refer to the *Profiler* documentation for further information.

`$this->output->cache();`

The CodeIgniter output library also controls caching. For more information, please see the *caching documentation*.

Parsing Execution Variables

CodeIgniter will parse the pseudo-variables {elapsed_time} and {memory_usage} in your output by default. To disable this, set the `$parse_exec_vars` class property to FALSE in your controller.

```
$this->output->parse_exec_vars = FALSE;
```

10.13.18 Pagination Class

CodeIgniter's Pagination class is very easy to use, and it is 100% customizable, either dynamically or via stored preferences.

If you are not familiar with the term “pagination”, it refers to links that allows you to navigate from page to page, like this:

```
« First < 1 2 3 4 5 > Last »
```

Example

Here is a simple example showing how to create pagination in one of your *controller* functions:

```
$this->load->library('pagination');

$config['base_url'] = 'http://example.com/index.php/test/page/';
$config['total_rows'] = 200;
$config['per_page'] = 20;

$this->pagination->initialize($config);

echo $this->pagination->create_links();
```

Notes

The `$config` array contains your configuration variables. It is passed to the `$this->pagination->initialize` function as shown above. Although there are some twenty items you can configure, at minimum you need the three shown. Here is a description of what those items represent:

- **base_url** This is the full URL to the controller class/function containing your pagination. In the example above, it is pointing to a controller called “Test” and a function called “page”. Keep in mind that you can *re-route your URI* if you need a different structure.
- **total_rows** This number represents the total rows in the result set you are creating pagination for. Typically this number will be the total rows that your database query returned.
- **per_page** The number of items you intend to show per page. In the above example, you would be showing 20 items per page.

The `create_links()` function returns an empty string when there is no pagination to show.

Setting preferences in a config file

If you prefer not to set preferences using the above method, you can instead put them into a config file. Simply create a new file called `pagination.php`, add the `$config` array in that file. Then save the file in: `config/pagination.php` and it will be used automatically. You will NOT need to use the `$this->pagination->initialize` function if you save your preferences in a config file.

Customizing the Pagination

The following is a list of all the preferences you can pass to the initialization function to tailor the display.

```
$config['uri_segment'] = 3;
```

The pagination function automatically determines which segment of your URI contains the page number. If you need something different you can specify it.

```
$config['num_links'] = 2;
```

The number of “digit” links you would like before and after the selected page number. For example, the number 2 will place two digits on either side, as in the example links at the very top of this page.

```
$config['use_page_numbers'] = TRUE;
```

By default, the URI segment will use the starting index for the items you are paginating. If you prefer to show the actual page number, set this to TRUE.

```
$config['page_query_string'] = TRUE;
```

By default, the pagination library assume you are using *URI Segments*, and constructs your links something like

```
http://example.com/index.php/test/page/20
```

If you have `$config['enable_query_strings']` set to TRUE your links will automatically be re-written using Query Strings. This option can also be explicitly set. Using `$config['page_query_string']` set to TRUE, the pagination link will become.

```
http://example.com/index.php?c=test&m=page&per_page=20
```

Note that “per_page” is the default query string passed, however can be configured using `$config['query_string_segment'] = 'your_string'`

```
$config['reuse_query_string'] = FALSE;
```

By default your Query String arguments (nothing to do with other query string options) will be ignored. Setting this config to TRUE will add existing query string arguments back into the URL after the URI segment and before the suffix

```
http://example.com/index.php/test/page/20?query=search%term
```

This helps you mix together normal *URI Segments* as well as query string arguments, which until 3.0 was not possible.

```
$config['prefix'] = '';
```

A custom prefix added to the path. The prefix value will be right before the offset segment.

```
$config['suffix'] = '';
```

A custom suffix added to the path. The suffix value will be right after the offset segment.

Adding Enclosing Markup

If you would like to surround the entire pagination with some markup you can do it with these two prefs:

```
$config['full_tag_open'] = '<p>';
```

The opening tag placed on the left side of the entire result.

```
$config['full_tag_close'] = '</p>';
```

The closing tag placed on the right side of the entire result.

Customizing the First Link

```
$config['first_link'] = 'First';
```

The text you would like shown in the “first” link on the left. If you do not want this link rendered, you can set its value to FALSE.

```
$config['first_tag_open'] = '<div>';
```

The opening tag for the “first” link.

```
$config['first_tag_close'] = '</div>';
```

The closing tag for the “first” link.

Customizing the Last Link

```
$config['last_link'] = 'Last';
```

The text you would like shown in the “last” link on the right. If you do not want this link rendered, you can set its value to FALSE.

```
$config['last_tag_open'] = '<div>';
```

The opening tag for the “last” link.

```
$config['last_tag_close'] = '</div>';
```

The closing tag for the “last” link.

Customizing the “Next” Link

```
$config['next_link'] = '&gt;';
```

The text you would like shown in the “next” page link. If you do not want this link rendered, you can set its value to FALSE.

```
$config['next_tag_open'] = '<div>';
```

The opening tag for the “next” link.

```
$config['next_tag_close'] = '</div>';
```

The closing tag for the “next” link.

Customizing the “Previous” Link

```
$config['prev_link'] = '&lt;';
```

The text you would like shown in the “previous” page link. If you do not want this link rendered, you can set its value to FALSE.

```
$config['prev_tag_open'] = '<div>';
```

The opening tag for the “previous” link.

```
$config['prev_tag_close'] = '</div>';
```

The closing tag for the “previous” link.

Customizing the “Current Page” Link

```
$config['cur_tag_open'] = '<b>';
```

The opening tag for the “current” link.

```
$config['cur_tag_close'] = '</b>';
```

The closing tag for the “current” link.

Customizing the “Digit” Link

```
$config['num_tag_open'] = '<div>';
```

The opening tag for the “digit” link.

```
$config['num_tag_close'] = '</div>';
```

The closing tag for the “digit” link.

Hiding the Pages

If you wanted to not list the specific pages (for example, you only want “next” and “previous” links), you can suppress their rendering by adding:

```
$config['display_pages'] = FALSE;
```

Adding attributes to anchors

If you want to add an extra attribute to be added to every link rendered by the pagination class, you can set them as key/value pairs in the “attributes” config

```
// Produces: class="myclass"
$config['attributes'] = array('class' => 'myclass');
```

: Usage of the old method of setting classes via “anchor_class” is deprecated.

Disabling the “rel” attribute

By default the rel attribute is dynamically generated and appended to the appropriate anchors. If for some reason you want to turn it off, you can pass boolean FALSE as a regular attribute

```
$config['attributes']['rel'] = FALSE;
```

10.13.19 Template Parser Class

The Template Parser Class enables you to parse pseudo-variables contained within your view files. It can parse simple variables or variable tag pairs. If you’ve never used a template engine, pseudo-variables look like this:

```
<html>
<head>
<title>{blog_title}</title>
</head>
<body>

<h3>{blog_heading}</h3>

{blog_entries}
<h5>{title}</h5>
<p>{body}</p>
{/blog_entries}
</body>
</html>
```

These variables are not actual PHP variables, but rather plain text representations that allow you to eliminate PHP from your templates (view files).

: CodeIgniter does **not** require you to use this class since using pure PHP in your view pages lets them run a little

faster. However, some developers prefer to use a template engine if they work with designers who they feel would find some confusion working with PHP.

: The Template Parser Class is **not** a full-blown template parsing solution. We've kept it very lean on purpose in order to maintain maximum performance.

Initializing the Class

Like most other classes in CodeIgniter, the Parser class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('parser');
```

Once loaded, the Parser library object will be available using: `$this->parser`

The following functions are available in this library:

`$this->parser->parse()`

This method accepts a template name and data array as input, and it generates a parsed version. Example:

```
$this->load->library('parser');

$data = array(
    'blog_title' => 'My Blog Title',
    'blog_heading' => 'My Blog Heading'
);

$this->parser->parse('blog_template', $data);
```

The first parameter contains the name of the *view file* (in this example the file would be called `blog_template.php`), and the second parameter contains an associative array of data to be replaced in the template. In the above example, the template would contain two variables: `{blog_title}` and `{blog_heading}`

There is no need to “echo” or do something with the data returned by `$this->parser->parse()`. It is automatically passed to the output class to be sent to the browser. However, if you do want the data returned instead of sent to the output class you can pass `TRUE` (boolean) to the third parameter:

```
$string = $this->parser->parse('blog_template', $data, TRUE);
```

`$this->parser->parse_string()`

This method works exactly like `parse()`, only accepts a string as the first parameter in place of a view file.

Variable Pairs

The above example code allows simple variables to be replaced. What if you would like an entire block of variables to be repeated, with each iteration containing new values? Consider the template example we showed at the top of the page:

```
<html>
<head>
<title>{blog_title}</title>
</head>
<body>

<h3>{blog_heading}</h3>

{blog_entries}
<h5>{title}</h5>
<p>{body}</p>
{/blog_entries}
</body>
</html>
```

In the above code you'll notice a pair of variables: {blog_entries} data... {/blog_entries}. In a case like this, the entire chunk of data between these pairs would be repeated multiple times, corresponding to the number of rows in a result.

Parsing variable pairs is done using the identical code shown above to parse single variables, except, you will add a multi-dimensional array corresponding to your variable pair data. Consider this example:

```
$this->load->library('parser');

$data = array(
    'blog_title'    => 'My Blog Title',
    'blog_heading'  => 'My Blog Heading',
    'blog_entries' => array(
        array('title' => 'Title 1', 'body' => 'Body 1'),
        array('title' => 'Title 2', 'body' => 'Body 2'),
        array('title' => 'Title 3', 'body' => 'Body 3'),
        array('title' => 'Title 4', 'body' => 'Body 4'),
        array('title' => 'Title 5', 'body' => 'Body 5')
    )
);

$this->parser->parse('blog_template', $data);
```

If your “pair” data is coming from a database result, which is already a multi-dimensional array, you can simply use the database result_array() function:

```
$query = $this->db->query("SELECT * FROM blog");

$this->load->library('parser');

$data = array(
    'blog_title'    => 'My Blog Title',
    'blog_heading'  => 'My Blog Heading',
    'blog_entries' => $query->result_array()
);

$this->parser->parse('blog_template', $data);
```

10.13.20 Security Class

The Security Class contains methods that help you create a secure application, processing input data for security.

XSS Filtering

CodeIgniter comes with a Cross Site Scripting Hack prevention filter which can either run automatically to filter all POST and COOKIE data that is encountered, or you can run it on a per item basis. By default it does **not** run globally since it requires a bit of processing overhead, and since you may not need it in all cases.

The XSS filter looks for commonly used techniques to trigger Javascript or other types of code that attempt to hijack cookies or do other malicious things. If anything disallowed is encountered it is rendered safe by converting the data to character entities.

Note: This function should only be used to deal with data upon submission. It's not something that should be used for general runtime processing since it requires a fair amount of processing overhead.

To filter data through the XSS filter use this function:

`$this->security->xss_clean()`

Here is an usage example:

```
$data = $this->security->xss_clean($data);
```

If you want the filter to run automatically every time it encounters POST or COOKIE data you can enable it by opening your application/config/config.php file and setting this:

```
$config['global_xss_filtering'] = TRUE;
```

Note: If you use the form validation class, it gives you the option of XSS filtering as well.

An optional second parameter, `is_image`, allows this function to be used to test images for potential XSS attacks, useful for file upload security. When this second parameter is set to TRUE, instead of returning an altered string, the function returns TRUE if the image is safe, and FALSE if it contained potentially malicious information that a browser may attempt to execute.

```
if ($this->security->xss_clean($file, TRUE) === FALSE)
{
    // file failed the XSS test
}
```

`$this->security->sanitize_filename()`

When accepting filenames from user input, it is best to sanitize them to prevent directory traversal and other security related issues. To do so, use the `sanitize_filename()` method of the Security class. Here is an example:

```
$filename = $this->security->sanitize_filename($this->input->post('filename'));
```

If it is acceptable for the user input to include relative paths, e.g. `file/in/some/approved/folder.txt`, you can set the second optional parameter, `$relative_path` to TRUE.

```
$filename = $this->security->sanitize_filename($this->input->post('filename'), TRUE);
```

Cross-site request forgery (CSRF)

You can enable CSRF protection by opening your application/config/config.php file and setting this:

```
$config['csrf_protection'] = TRUE;
```

If you use the *form helper*, then `form_open()` will automatically insert a hidden csrf field in your forms. If not, then you can use `csrf_get_token_name()` and `csrf_get_hash()`

```
$csrf = array(
    'name' => $this->security->csrf_get_token_name(),
    'hash' => $this->security->csrf_get_hash()
);

...

<input type="hidden" name="<?=$csrf['name'];?>" value="<?=$csrf['hash'];?>" />
```

Tokens may be either regenerated on every submission (default) or kept the same throughout the life of the CSRF cookie. The default regeneration of tokens provides stricter security, but may result in usability concerns as other tokens become invalid (back/forward navigation, multiple tabs/windows, asynchronous actions, etc). You may alter this behavior by editing the following config parameter

```
$config['csrf_regeneration'] = TRUE;
```

Select URIs can be whitelisted from csrf protection (for example API endpoints expecting externally POSTed content). You can add these URIs by editing the 'csrf_exclude_uris' config parameter:

```
$config['csrf_exclude_uris'] = array('api/person/add');
```

`$this->security->get_csrf_token_name()`

Returns the CSRF token name, which is set by `$config['csrf_token_name']`.

`$this->security->get_csrf_hash()`

Returns the CSRF hash value. Useful in combination with `get_csrf_token_name()` for manually building forms or sending valid AJAX POST requests.

10.13.21 Session Driver

The Session class permits you maintain a user's "state" and track their activity while they browse your site. CodeIgniter offers two default session drivers: the classic Cookie Driver, and the Native Driver, which supports usage of the native PHP Session mechanism. In addition, you may create your own Custom Drivers to store session data however you wish, while still taking advantage of the features of the Session class.

Initializing a Session

Sessions will typically run globally with each page load, so the session class must either be *initialized* in your *controller* constructors, or it can be *auto-loaded* by the system. For the most part the session class will run unattended in the background, so simply initializing the class will cause it to read, create, and update sessions.

To initialize the Session class manually in your controller constructor, use the `$this->load->driver` function:

```
$this->load->driver('session');
```

Once loaded, the Sessions library object will be available using: `$this->session`

How do Sessions work?

When a page is loaded, the session class will check to see if valid session data exists in the user's session. If sessions data does **not** exist (or if it has expired) a new session will be created and saved. If a session does exist, its information will be updated. With each update, the session_id will be regenerated.

It's important for you to understand that once initialized, the Session class runs automatically. There is nothing you need to do to cause the above behavior to happen. You can, as you'll see below, work with session data or even add your own data to a user's session, but the process of reading, writing, and updating a session is automatic.

What is Session Data?

A *session*, as far as CodeIgniter is concerned, is simply an array containing the following information:

- The user's unique Session ID (this is a statistically random string with very strong entropy, hashed with MD5 for portability, and regenerated (by default) every five minutes)
- The user's IP Address
- The user's User Agent data (the first 120 characters of the browser data string)
- The "last activity" time stamp.

The above data is stored in a cookie as a serialized array with this prototype:

```
[array]
(
    'session_id'    => random hash,
    'ip_address'    => 'string - user IP address',
    'user_agent'    => 'string - user agent data',
    'last_activity' => timestamp
)
```

: Sessions are only updated every five minutes by default to reduce processor load. If you repeatedly reload a page you'll notice that the "last activity" time only updates if five minutes or more has passed since the last time the cookie was written. This time is configurable by changing the `$config['sess_time_to_update']` line in your `system/config/config.php` file.

Retrieving Session Data

Any piece of information from the session array is available using the following function:

```
$this->session->userdata('item');
```

Where `item` is the array index corresponding to the item you wish to fetch. For example, to fetch the session ID you will do this:

```
$session_id = $this->session->userdata('session_id');
```

: The function returns NULL if the item you are trying to access does not exist.

Adding Custom Session Data

A useful aspect of the session array is that you can add your own data to it and it will be stored in the user's cookie. Why would you want to do this? Here's one example:

Let's say a particular user logs into your site. Once authenticated, you could add their username and email address to the session, making that data globally available to you without having to run a database query when you need it.

To add your data to the session array involves passing an array containing your new data to this function:

```
$this->session->set_userdata($array);
```

Where `$array` is an associative array containing your new data. Here's an example:

```
$newdata = array(
    'username' => 'johndoe',
    'email'    => 'johndoe@some-site.com',
    'logged_in' => TRUE
);

$this->session->set_userdata($newdata);
```

If you want to add userdata one value at a time, `set_userdata()` also supports this syntax.

```
$this->session->set_userdata('some_name', 'some_value');
```

If you want to verify that a userdata value exists, call `has_userdata()`.

```
$this->session->has_userdata('some_name');
```

Retrieving All Session Data

An array of all userdata can be retrieved as follows:

```
$this->session->all_userdata()
```

And returns an associative array like the following:

```
Array
(
    [session_id] => 4a5a5dca22728fb0a84364eeb405b601
    [ip_address] => 127.0.0.1
    [user_agent] => Mozilla/5.0 (Macintosh; U; Intel Mac OS X 10_6_7;
    [last_activity] => 1303142623
)
```

Removing Session Data

Just as `set_userdata()` can be used to add information into a session, `unset_userdata()` can be used to remove it, by passing the session key. For example, if you wanted to remove 'some_name' from your session information:

```
$this->session->unset_userdata('some_name');
```

This function can also be passed an associative array of items to unset.

```
$array_items = array('username' => '', 'email' => '');

$this->session->unset_userdata($array_items);
```

Flashdata

CodeIgniter supports “flashdata”, or session data that will only be available for the next server request, and are then automatically cleared. These can be very useful, and are typically used for informational or status messages (for example: “record 2 deleted”).

: Flash variables are prefaced with “flash_” so avoid this prefix in your own session names.

To add flashdata:

```
$this->session->set_flashdata('item', 'value');
```

You can also pass an array to `set_flashdata()`, in the same manner as `set_userdata()`.

To read a flashdata variable:

```
$this->session->flashdata('item');
```

An array of all flashdata can be retrieved as follows:

```
$this->session->all_flashdata();
```

If you find that you need to preserve a flashdata variable through an additional request, you can do so using the `keep_flashdata()` function. You can either pass a single item or an array of flashdata items to keep.

```
$this->session->keep_flashdata('item');
$this->session->keep_flashdata(array('item1', 'item2', 'item3'));
```

Tempdata

CodeIgniter also supports “tempdata”, or session data with a specific expiration time. After the value expires, or the session expires or is deleted, the value is automatically removed.

To add tempdata:

```
$expire = 300; // Expire in 5 minutes

$this->session->set_tempdata('item', 'value', $expire);
```

You can also pass an array to `set_tempdata()`:

```
$tempdata = array('newuser' => TRUE, 'message' => 'Thanks for joining!');

$this->session->set_tempdata($tempdata, '', $expire);
```

: If the expiration is omitted or set to 0, the default expiration of 5 minutes will be used.

To read a tempdata variable:

```
$this->session->tempdata('item');
```

If you need to remove a tempdata value before it expires, use `unset_tempdata()`:

```
$this->session->unset_tempdata('item');
```

Destroying a Session

To clear the current session:

```
$this->session->sess_destroy();
```

: This function should be the last one called, and even flash variables will no longer be available. If you only want some items destroyed and not all, use `unset_userdata()`.

Session Preferences

You'll find the following Session related preferences in your *application/config/config.php* file:

Preference	Default	Options	Description
sess_driver	cookie	cookie/native/	The initial session driver to load.
sess_valid_drivers	cookie, native	None	Additional valid drivers which may be loaded.
sess_cookie_name	sessionid	None	The name you want the session cookie saved as (data for Cookie driver or session ID for Native driver).
sess_expiration	7200	None	The number of seconds you would like the session to last. The default value is 2 hours (7200 seconds). If you would like a non-expiring session set the value to zero: 0
sess_expire_on_close	FALSE	TRUE/FALSE (boolean)	Whether to cause the session to expire automatically when the browser window is closed.
sess_encrypt_cookie	FALSE	TRUE/FALSE (boolean)	Whether to encrypt the session data (Cookie driver only).
sess_use_database	FALSE	TRUE/FALSE (boolean)	Whether to save the session data to a database. You must create the table before enabling this option (Cookie driver only).
sess_table_name	session	Any valid SQL table name	The name of the session database table (Cookie driver only).
sess_time_to_update	300	Time in seconds	This options controls how often the session class will regenerate itself and create a new session ID. Setting it to 0 will disable session ID regeneration.
sess_match_ip	FALSE	TRUE/FALSE (boolean)	Whether to match the user's IP address when reading the session data. Note that some ISPs dynamically changes the IP, so if you want a non-expiring session you will likely set this to FALSE.
sess_match_useragent	FALSE	TRUE/FALSE (boolean)	Whether to match the User Agent when reading the session data.

In addition to the values above, the cookie and native drivers apply the following configuration values shared by the *Input* and *Security* classes:

Preference	Default	Description
cookie_prefix	''	Set a cookie name prefix in order to avoid name collisions
cookie_domain	''	The domain for which the session is applicable
cookie_path	/	The path to which the session is applicable

Session Drivers

By default, the Cookie Driver is loaded when a session is initialized. However, any valid driver may be selected with the `$config['sess_driver']` line in your *config.php* file.

The session driver library comes with the cookie and native drivers installed, and Custom Drivers may also be installed by the user.

Typically, only one driver will be used at a time, but CodeIgniter does support loading multiple drivers. If a specific valid driver is called, it will be automatically loaded. Or, an additional driver may be explicitly loaded by calling `load_driver()`:

```
$this->session->load_driver('native');
```

The Session library keeps track of the most recently selected driver to call for driver methods. Normally, session class methods are called directly on the parent class, as illustrated above. However, any methods called through a specific driver will select that driver before invoking the parent method.

So, alternation between multiple drivers can be achieved by specifying which driver to use for each call:

```
$this->session->native->set_userdata('foo', 'bar');
```

```
$this->session->cookie->userdata('foo');
```

```
$this->session->native->unset_userdata('foo');
```

Notice in the previous example that the *native* userdata value 'foo' would be set to 'bar', which would NOT be returned by the call for the *cookie* userdata 'foo', nor would the *cookie* value be unset by the call to unset the *native* 'foo' value. The drivers maintain independent sets of values, regardless of key names.

A specific driver may also be explicitly selected for use by pursuant methods with the `select_driver()` call:

```
$this->session->select_driver('native');
```

```
$this->session->userdata('item');           // Uses the native driver
```

Cookie Driver

The Cookie driver stores session information for each user as serialized (and optionally encrypted) data in a cookie. It can also store the session data in a database table for added security, as this permits the session ID in the user's cookie to be matched against the stored session ID. By default only the cookie is saved. If you choose to use the database option you'll need to create the session table as indicated below.

If you have the encryption option enabled, the serialized array will be encrypted before being stored in the cookie, making the data highly secure and impervious to being read or altered by someone. More info regarding encryption can be *found here*, although the Session class will take care of initializing and encrypting the data automatically.

: Even if you are not using encrypted sessions, you must set an *encryption key* in your config file which is used to aid in preventing session data manipulation.

: Cookies can only hold 4KB of data, so be careful not to exceed the capacity. The encryption process in particular produces a longer data string than the original so keep careful track of how much data you are storing.

Saving Session Data to a Database While the session data array stored in the user's cookie contains a Session ID, unless you store session data in a database there is no way to validate it. For some applications that require little or no security, session ID validation may not be needed, but if your application requires security, validation is mandatory. Otherwise, an old session could be restored by a user modifying their cookies.

When session data is available in a database, every time a valid session is found in the user's cookie, a database query is performed to match it. If the session ID does not match, the session is destroyed. Session IDs can never be updated, they can only be generated when a new session is created.

In order to store sessions, you must first create a database table for this purpose. Here is the basic prototype (for MySQL) required by the session class:

```
CREATE TABLE IF NOT EXISTS `ci_sessions` (  
    session_id varchar(40) DEFAULT '0' NOT NULL,  
    ip_address varchar(45) DEFAULT '0' NOT NULL,  
    user_agent varchar(120) NOT NULL,  
    last_activity int(10) unsigned DEFAULT 0 NOT NULL,  
    user_data text NOT NULL,  
    PRIMARY KEY (session_id, ip_address, user_agent),  
    KEY `last_activity_idx` (`last_activity`)  
);
```

: By default the table is called `ci_sessions`, but you can name it anything you want as long as you update the `application/config/config.php` file so that it contains the name you have chosen. Once you have created your database table you can enable the database option in your `config.php` file as follows:

```
$config['sess_use_database'] = TRUE;
```

Once enabled, the Session class will store session data in the DB.

Make sure you've specified the table name in your config file as well:

```
$config['sess_table_name'] = 'ci_sessions';
```

: The Cookie driver has built-in garbage collection which clears out expired sessions so you do not need to write your own routine to do it.

Native Driver

The Native driver relies on native PHP sessions to store data in the `$_SESSION` superglobal array. All stored values continue to be available through `$_SESSION`, but flash- and temp- data items carry special prefixes.

Custom Drivers

You may also *create your own* custom session drivers. A session driver basically manages an array of name/value pairs with some sort of storage mechanism.

To make a new driver, extend `CI_Session_driver`. Overload the `initialize()` method and read or create session data. Then implement a save handler to write changed data to storage (`sess_save`), a destroy handler to remove deleted data (`sess_destroy`), a regenerate handler to make a new session ID (`sess_regenerate`), and an access handler to expose the data (`get_userdata`). Your initial class might look like:

```
class CI_Session_custom extends CI_Session_driver {  
    protected function initialize()  
    {  
        // Read existing session data or create a new one  
    }  
  
    public function sess_save()  
    {  
        // Save current data to storage  
    }  
}
```

```

    public function sess_destroy()
    {
        // Destroy the current session and clean up storage
    }

    public function sess_regenerate()
    {
        // Create new session ID
    }

    public function &get_userdata()
    {
        // Return a reference to your userdata array
    }
}

```

Notice that `get_userdata()` returns a reference so the parent library is accessing the same array the driver object is using. This saves memory and avoids synchronization issues during usage.

Put your driver in the `libraries/Session/drivers` folder anywhere in your package paths. This includes the application directory, the system directory, or any path you add with `$CI->load->add_package_path()`. Your driver must be named `CI_Session_<name>`, and your filename must be `Session_<name>.php`, preferably also capitalized, such as:

`CI_Session_foo` in `libraries/Session/drivers/Session_foo.php`

Then specify the driver by setting `'sess_driver'` in your `config.php` file or as a parameter when loading the `CI_Session` object:

```
$config['sess_driver'] = 'foo';
```

OR:

```
$CI->load->driver('session', array('sess_driver' => 'foo'));
```

The driver specified by `'sess_driver'` is automatically included as a valid driver. However, if you want to make a custom driver available as an option without making it the initially loaded driver, set `'sess_valid_drivers'` in your `config.php` file to an array including your driver name:

```
$config['sess_valid_drivers'] = array('sess_driver');
```

10.13.22 HTML Table Class

The Table Class provides functions that enable you to auto-generate HTML tables from arrays or database result sets.

Initializing the Class

Like most other classes in CodeIgniter, the Table class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('table');
```

Once loaded, the Table library object will be available using: `$this->table`

Examples

Here is an example showing how you can create a table from a multi-dimensional array. Note that the first array index will become the table heading (or you can set your own headings using the `set_heading()` function described in the function reference below).

```
$this->load->library('table');

$data = array(
    array('Name', 'Color', 'Size'),
    array('Fred', 'Blue', 'Small'),
    array('Mary', 'Red', 'Large'),
    array('John', 'Green', 'Medium')
);

echo $this->table->generate($data);
```

Here is an example of a table created from a database query result. The table class will automatically generate the headings based on the table names (or you can set your own headings using the `set_heading()` function described in the function reference below).

```
$this->load->library('table');

$query = $this->db->query("SELECT * FROM my_table");

echo $this->table->generate($query);
```

Here is an example showing how you might create a table using discrete parameters:

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');

$this->table->add_row('Fred', 'Blue', 'Small');
$this->table->add_row('Mary', 'Red', 'Large');
$this->table->add_row('John', 'Green', 'Medium');

echo $this->table->generate();
```

Here is the same example, except instead of individual parameters, arrays are used:

```
$this->load->library('table');

$this->table->set_heading(array('Name', 'Color', 'Size'));

$this->table->add_row(array('Fred', 'Blue', 'Small'));
$this->table->add_row(array('Mary', 'Red', 'Large'));
$this->table->add_row(array('John', 'Green', 'Medium'));

echo $this->table->generate();
```

Changing the Look of Your Table

The Table Class permits you to set a table template with which you can specify the design of your layout. Here is the template prototype:

```
$tmpl = array (
    'table_open'          => '<table border="0" cellpadding="4" cellspacing="0">',
```

```

        'heading_row_start'    => '<tr>',
        'heading_row_end'      => '</tr>',
        'heading_cell_start'    => '<th>',
        'heading_cell_end'      => '</th>',

        'row_start'            => '<tr>',
        'row_end'              => '</tr>',
        'cell_start'           => '<td>',
        'cell_end'             => '</td>',

        'row_alt_start'        => '<tr>',
        'row_alt_end'          => '</tr>',
        'cell_alt_start'       => '<td>',
        'cell_alt_end'         => '</td>',

        'table_close'          => '</table>'
    );

$this->table->set_template($tmpl);

```

: You'll notice there are two sets of "row" blocks in the template. These permit you to create alternating row colors or design elements that alternate with each iteration of the row data.

You are NOT required to submit a complete template. If you only need to change parts of the layout you can simply submit those elements. In this example, only the table opening tag is being changed:

```

$tmpl = array ( 'table_open'  => '<table border="1" cellpadding="2" cellspacing="1" class="mytable">'

$this->table->set_template($tmpl);

```

You can also set defaults for these in a config file.

Function Reference

`$this->table->generate()`

Returns a string containing the generated table. Accepts an optional parameter which can be an array or a database result object.

`$this->table->set_caption()`

Permits you to add a caption to the table.

```

$this->table->set_caption('Colors');

```

`$this->table->set_heading()`

Permits you to set the table heading. You can submit an array or discrete params:

```

$this->table->set_heading('Name', 'Color', 'Size');

$this->table->set_heading(array('Name', 'Color', 'Size'));

```

`$this->table->add_row()`

Permits you to add a row to your table. You can submit an array or discrete params:

```
$this->table->add_row('Blue', 'Red', 'Green');

$this->table->add_row(array('Blue', 'Red', 'Green'));
```

If you would like to set an individual cell's tag attributes, you can use an associative array for that cell. The associative key 'data' defines the cell's data. Any other key => val pairs are added as key='val' attributes to the tag:

```
$cell = array('data' => 'Blue', 'class' => 'highlight', 'colspan' => 2);
$this->table->add_row($cell, 'Red', 'Green');

// generates
// <td class='highlight' colspan='2'>Blue</td><td>Red</td><td>Green</td>
```

`$this->table->make_columns()`

This function takes a one-dimensional array as input and creates a multi-dimensional array with a depth equal to the number of columns desired. This allows a single array with many elements to be displayed in a table that has a fixed column count. Consider this example:

```
$list = array('one', 'two', 'three', 'four', 'five', 'six', 'seven', 'eight', 'nine', 'ten', 'eleven');
$new_list = $this->table->make_columns($list, 3);

$this->table->generate($new_list);

// Generates a table with this prototype

<table border="0" cellpadding="4" cellspacing="0">
<tr>
<td>one</td><td>two</td><td>three</td>
</tr><tr>
<td>four</td><td>five</td><td>six</td>
</tr><tr>
<td>seven</td><td>eight</td><td>nine</td>
</tr><tr>
<td>ten</td><td>eleven</td><td>twelve</td></tr>
</table>
```

`$this->table->set_template()`

Permits you to set your template. You can submit a full or partial template.

```
$tmpl = array ( 'table_open' => '<table border="1" cellpadding="2" cellspacing="1" class="mytable">');

$this->table->set_template($tmpl);
```

`$this->table->set_empty()`

Let's you set a default value for use in any table cells that are empty. You might, for example, set a non-breaking space:

```
$this->table->set_empty("&nbsp;");
```

`$this->table->clear()`

Lets you clear the table heading and row data. If you need to show multiple tables with different data you should to call this function after each table has been generated to empty the previous table information. Example:

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');
$this->table->add_row('Fred', 'Blue', 'Small');
$this->table->add_row('Mary', 'Red', 'Large');
$this->table->add_row('John', 'Green', 'Medium');

echo $this->table->generate();

$this->table->clear();

$this->table->set_heading('Name', 'Day', 'Delivery');
$this->table->add_row('Fred', 'Wednesday', 'Express');
$this->table->add_row('Mary', 'Monday', 'Air');
$this->table->add_row('John', 'Saturday', 'Overnight');

echo $this->table->generate();
```

`$this->table->function`

Allows you to specify a native PHP function or a valid function array object to be applied to all cell data.

```
$this->load->library('table');

$this->table->set_heading('Name', 'Color', 'Size');
$this->table->add_row('Fred', '<strong>Blue</strong>', 'Small');

$this->table->function = 'htmlspecialchars';
echo $this->table->generate();
```

In the above example, all cell data would be ran through PHP's `htmlspecialchars()` function, resulting in:

```
<td>Fred</td><td>&lt;strong&gt;Blue&lt;/strong&gt;</td><td>Small</td>
```

10.13.23 Trackback Class

The Trackback Class provides functions that enable you to send and receive Trackback data.

If you are not familiar with Trackbacks you'll find more information [here](#).

Initializing the Class

Like most other classes in CodeIgniter, the Trackback class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('trackback');
```

Once loaded, the Trackback library object will be available using: `$this->trackback`

Sending Trackbacks

A Trackback can be sent from any of your controller functions using code similar to this example:

```
$this->load->library('trackback');

$tb_data = array(
    'ping_url'  => 'http://example.com/trackback/456',
    'url'       => 'http://www.my-example.com/blog/entry/123',
    'title'     => 'The Title of My Entry',
    'excerpt'   => 'The entry content.',
    'blog_name' => 'My Blog Name',
    'charset'   => 'utf-8'
);

if ( ! $this->trackback->send($tb_data) )
{
    echo $this->trackback->display_errors();
}
else
{
    echo 'Trackback was sent!';
}
```

Description of array data:

- **ping_url** - The URL of the site you are sending the Trackback to. You can send Trackbacks to multiple URLs by separating each URL with a comma.
- **url** - The URL to YOUR site where the weblog entry can be seen.
- **title** - The title of your weblog entry.
- **excerpt** - The content of your weblog entry. Note: the Trackback class will automatically send only the first 500 characters of your entry. It will also strip all HTML.
- **blog_name** - The name of your weblog.
- **charset** - The character encoding your weblog is written in. If omitted, UTF-8 will be used.

The Trackback sending function returns TRUE/FALSE (boolean) on success or failure. If it fails, you can retrieve the error message using:

```
$this->trackback->display_errors();
```

Receiving Trackbacks

Before you can receive Trackbacks you must create a weblog. If you don't have a blog yet there's no point in continuing.

Receiving Trackbacks is a little more complex than sending them, only because you will need a database table in which to store them, and you will need to validate the incoming trackback data. You are encouraged to implement a thorough validation process to guard against spam and duplicate data. You may also want to limit the number of Trackbacks you allow from a particular IP within a given span of time to further curtail spam. The process of receiving a Trackback is quite simple; the validation is what takes most of the effort.

Your Ping URL

In order to accept Trackbacks you must display a Trackback URL next to each one of your weblog entries. This will be the URL that people will use to send you Trackbacks (we will refer to this as your “Ping URL”).

Your Ping URL must point to a controller function where your Trackback receiving code is located, and the URL must contain the ID number for each particular entry, so that when the Trackback is received you’ll be able to associate it with a particular entry.

For example, if your controller class is called Trackback, and the receiving function is called receive, your Ping URLs will look something like this:

```
http://example.com/index.php/trackback/receive/entry_id
```

Where entry_id represents the individual ID number for each of your entries.

Creating a Trackback Table

Before you can receive Trackbacks you must create a table in which to store them. Here is a basic prototype for such a table:

```
CREATE TABLE trackbacks (
  tb_id int(10) unsigned NOT NULL auto_increment,
  entry_id int(10) unsigned NOT NULL default 0,
  url varchar(200) NOT NULL,
  title varchar(100) NOT NULL,
  excerpt text NOT NULL,
  blog_name varchar(100) NOT NULL,
  tb_date int(10) NOT NULL,
  ip_address varchar(45) NOT NULL,
  PRIMARY KEY `tb_id` (`tb_id`),
  KEY `entry_id` (`entry_id`)
);
```

The Trackback specification only requires four pieces of information to be sent in a Trackback (url, title, excerpt, blog_name), but to make the data more useful we’ve added a few more fields in the above table schema (date, IP address, etc.).

Processing a Trackback

Here is an example showing how you will receive and process a Trackback. The following code is intended for use within the controller function where you expect to receive Trackbacks.

```
$this->load->library('trackback');
$this->load->database();

if ($this->uri->segment(3) == FALSE)
{
    $this->trackback->send_error("Unable to determine the entry ID");
}

if ( ! $this->trackback->receive())
{
    $this->trackback->send_error("The Trackback did not contain valid data");
}

$data = array(
```

```
'tb_id'      => '',
'entry_id'   => $this->uri->segment(3),
'url'        => $this->trackback->data('url'),
'title'      => $this->trackback->data('title'),
'excerpt'    => $this->trackback->data('excerpt'),
'blog_name'  => $this->trackback->data('blog_name'),
'tb_date'    => time(),
'ip_address' => $this->input->ip_address()
);

$sql = $this->db->insert_string('trackbacks', $data);
$this->db->query($sql);

$this->trackback->send_success();
```

Notes:

The entry ID number is expected in the third segment of your URL. This is based on the URI example we gave earlier:

`http://example.com/index.php/trackback/receive/entry_id`

Notice the `entry_id` is in the third URI segment, which you can retrieve using:

```
$this->uri->segment(3);
```

In our Trackback receiving code above, if the third segment is missing, we will issue an error. Without a valid entry ID, there's no reason to continue.

The `$this->trackback->receive()` function is simply a validation function that looks at the incoming data and makes sure it contains the four pieces of data that are required (url, title, excerpt, blog_name). It returns TRUE on success and FALSE on failure. If it fails you will issue an error message.

The incoming Trackback data can be retrieved using this function:

```
$this->trackback->data('item')
```

Where item represents one of these four pieces of info: url, title, excerpt, or blog_name

If the Trackback data is successfully received, you will issue a success message using:

```
$this->trackback->send_success();
```

: The above code contains no data validation, which you are encouraged to add.

10.13.24 Typography Class

The Typography Class provides functions that help you format text.

Initializing the Class

Like most other classes in CodeIgniter, the Typography class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('typography');
```

Once loaded, the Typography library object will be available using: `$this->typography`

auto_typography()

Formats text so that it is semantically and typographically correct HTML. Takes a string as input and returns it with the following formatting:

- Surrounds paragraphs within <p></p> (looks for double line breaks to identify paragraphs).
- Single line breaks are converted to
, except those that appear within <pre> tags.
- Block level elements, like <div> tags, are not wrapped within paragraphs, but their contained text is if it contains paragraphs.
- Quotes are converted to correctly facing curly quote entities, except those that appear within tags.
- Apostrophes are converted to curly apostrophe entities.
- Double dashes (either like – this or like–this) are converted to em—dashes.
- Three consecutive periods either preceding or following a word are converted to ellipsis...
- Double spaces following sentences are converted to non-breaking spaces to mimic double spacing.

Usage example:

```
$string = $this->typography->auto_typography($string);
```

Parameters

There is one optional parameters that determines whether the parser should reduce more than two consecutive line breaks down to two. Use boolean TRUE or FALSE.

By default the parser does not reduce line breaks. In other words, if no parameters are submitted, it is the same as doing this:

```
$string = $this->typography->auto_typography($string, FALSE);
```

: Typographic formatting can be processor intensive, particularly if you have a lot of content being formatted. If you choose to use this function you may want to consider *caching* your pages.

format_characters()

This function is similar to the auto_typography function above, except that it only does character conversion:

- Quotes are converted to correctly facing curly quote entities, except those that appear within tags.
- Apostrophes are converted to curly apostrophe entities.
- Double dashes (either like – this or like–this) are converted to em—dashes.
- Three consecutive periods either preceding or following a word are converted to ellipsis...
- Double spaces following sentences are converted to non-breaking spaces to mimic double spacing.

Usage example:

```
$string = $this->typography->format_characters($string);
```

nl2br_except_pre()

Converts newlines to
 tags unless they appear within <pre> tags. This function is identical to the native PHP nl2br() function, except that it ignores <pre> tags.

Usage example:

```
$string = $this->typography->nl2br_except_pre($string);
```

protect_braced_quotes

When using the Typography library in conjunction with the Template Parser library it can often be desirable to protect single and double quotes within curly braces. To enable this, set the protect_braced_quotes class property to TRUE.

Usage example:

```
$this->load->library('typography');  
$this->typography->protect_braced_quotes = TRUE;
```

10.13.25 Unit Testing Class

Unit testing is an approach to software development in which tests are written for each function in your application. If you are not familiar with the concept you might do a little googling on the subject.

CodeIgniter's Unit Test class is quite simple, consisting of an evaluation function and two result functions. It's not intended to be a full-blown test suite but rather a simple mechanism to evaluate your code to determine if it is producing the correct data type and result.

Initializing the Class

Like most other classes in CodeIgniter, the Unit Test class is initialized in your controller using the \$this->load->library function:

```
$this->load->library('unit_test');
```

Once loaded, the Unit Test object will be available using: \$this->unit

Running Tests

Running a test involves supplying a test and an expected result to the following function:

`$this->unit->run(test, expected result, 'test name', 'notes');`

Where test is the result of the code you wish to test, expected result is the data type you expect, test name is an optional name you can give your test, and notes are optional notes. Example:

```
$test = 1 + 1;  
  
$expected_result = 2;  
  
$test_name = 'Adds one plus one';  
  
$this->unit->run($test, $expected_result, $test_name);
```

The expected result you supply can either be a literal match, or a data type match. Here's an example of a literal:

```
$this->unit->run('Foo', 'Foo');
```

Here is an example of a data type match:

```
$this->unit->run('Foo', 'is_string');
```

Notice the use of “is_string” in the second parameter? This tells the function to evaluate whether your test is producing a string as the result. Here is a list of allowed comparison types:

- is_object
- is_string
- is_bool
- is_true
- is_false
- is_int
- is_numeric
- is_float
- is_double
- is_array
- is_null

Generating Reports

You can either display results after each test, or you can run several tests and generate a report at the end. To show a report directly simply echo or return the run function:

```
echo $this->unit->run($test, $expected_result);
```

To run a full report of all tests, use this:

```
echo $this->unit->report();
```

The report will be formatted in an HTML table for viewing. If you prefer the raw data you can retrieve an array using:

```
echo $this->unit->result();
```

Strict Mode

By default the unit test class evaluates literal matches loosely. Consider this example:

```
$this->unit->run(1, TRUE);
```

The test is evaluating an integer, but the expected result is a boolean. PHP, however, due to its loose data-typing will evaluate the above code as TRUE using a normal equality test:

```
if (1 == TRUE) echo 'This evaluates as true';
```

If you prefer, you can put the unit test class in to strict mode, which will compare the data type as well as the value:

```
if (1 === TRUE) echo 'This evaluates as FALSE';
```

To enable strict mode use this:

```
$this->unit->use_strict(TRUE);
```

Enabling/Disabling Unit Testing

If you would like to leave some testing in place in your scripts, but not have it run unless you need it, you can disable unit testing using:

```
$this->unit->active(FALSE)
```

Unit Test Display

When your unit test results display, the following items show by default:

- Test Name (test_name)
- Test Datatype (test_datatype)
- Expected Datatype (res_datatype)
- Result (result)
- File Name (file)
- Line Number (line)
- Any notes you entered for the test (notes)

You can customize which of these items get displayed by using `$this->unit->set_test_items()`. For example, if you only wanted the test name and the result displayed:

Customizing displayed tests

```
$this->unit->set_test_items(array('test_name', 'result'));
```

Creating a Template

If you would like your test results formatted differently then the default you can set your own template. Here is an example of a simple template. Note the required pseudo-variables:

```
$str = '  
<table border="0" cellpadding="4" cellspacing="1">  
    {rows}  
        <tr>  
            <td>{item}</td>  
            <td>{result}</td>  
        </tr>  
    {/rows}  
</table>';
```

```
$this->unit->set_template($str);
```

: Your template must be declared **before** running the unit test process.

10.13.26 URI Class

The URI Class provides functions that help you retrieve information from your URI strings. If you use URI routing, you can also retrieve information about the re-routed segments.

: This class is initialized automatically by the system so there is no need to do it manually.

`$this->uri->segment(n)`

Permits you to retrieve a specific segment. Where *n* is the segment number you wish to retrieve. Segments are numbered from left to right. For example, if your full URL is this:

```
http://example.com/index.php/news/local/metro/crime_is_up
```

The segment numbers would be this:

1. news
2. local
3. metro
4. crime_is_up

By default the function returns NULL if the segment does not exist. There is an optional second parameter that permits you to set your own default value if the segment is missing. For example, this would tell the function to return the number zero in the event of failure:

```
$product_id = $this->uri->segment(3, 0);
```

It helps avoid having to write code like this:

```
if ($this->uri->segment(3) === FALSE)
{
    $product_id = 0;
}
else
{
    $product_id = $this->uri->segment(3);
}
```

`$this->uri->rsegment(n)`

This function is identical to the previous one, except that it lets you retrieve a specific segment from your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->slash_segment(n)`

This function is almost identical to `$this->uri->segment()`, except it adds a trailing and/or leading slash based on the second parameter. If the parameter is not used, a trailing slash added. Examples:

```
$this->uri->slash_segment(3);  
$this->uri->slash_segment(3, 'leading');  
$this->uri->slash_segment(3, 'both');
```

Returns:

1. segment/
2. /segment
3. /segment/

`$this->uri->slash_rsegment(n)`

This function is identical to the previous one, except that it lets you add slashes a specific segment from your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->uri_to_assoc(n)`

This function lets you turn URI segments into an associative array of key/value pairs. Consider this URI:

```
index.php/user/search/name/joe/location/UK/gender/male
```

Using this function you can turn the URI into an associative array with this prototype:

```
[array]  
(  
    'name' => 'joe'  
    'location' => 'UK'  
    'gender' => 'male'  
)
```

The first parameter of the function lets you set an offset. By default it is set to 3 since your URI will normally contain a controller/function in the first and second segments. Example:

```
$array = $this->uri->uri_to_assoc(3);
```

```
echo $array['name'];
```

The second parameter lets you set default key names, so that the array returned by the function will always contain expected indexes, even if missing from the URI. Example:

```
$default = array('name', 'gender', 'location', 'type', 'sort');
```

```
$array = $this->uri->uri_to_assoc(3, $default);
```

If the URI does not contain a value in your default, an array index will be set to that name, with a value of FALSE.

Lastly, if a corresponding value is not found for a given key (if there is an odd number of URI segments) the value will be set to FALSE (boolean).

`$this->uri->ruri_to_assoc(n)`

This function is identical to the previous one, except that it creates an associative array using the re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->assoc_to_uri()`

Takes an associative array as input and generates a URI string from it. The array keys will be included in the string.
Example:

```
$array = array('product' => 'shoes', 'size' => 'large', 'color' => 'red');

$str = $this->uri->assoc_to_uri($array);

// Produces: product/shoes/size/large/color/red
```

`$this->uri->uri_string()`

Returns a string with the complete URI. For example, if this is your full URL:

```
http://example.com/index.php/news/local/345
```

The function would return this:

```
news/local/345
```

`$this->uri->ruri_string()`

This function is identical to the previous one, except that it returns the re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->total_segments()`

Returns the total number of segments.

`$this->uri->total_rsegments()`

This function is identical to the previous one, except that it returns the total number of segments in your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

`$this->uri->segment_array()`

Returns an array containing the URI segments. For example:

```
$segs = $this->uri->segment_array();

foreach ($segs as $segment)
{
    echo $segment;
    echo '<br />';
}
```

`$this->uri->rsegment_array()`

This function is identical to the previous one, except that it returns the array of segments in your re-routed URI in the event you are using CodeIgniter's *URI Routing* feature.

10.13.27 User Agent Class

The User Agent Class provides functions that help identify information about the browser, mobile device, or robot visiting your site. In addition you can get referrer information as well as language and supported character-set information.

Initializing the Class

Like most other classes in CodeIgniter, the User Agent class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('user_agent');
```

Once loaded, the object will be available using: `$this->agent`

User Agent Definitions

The user agent name definitions are located in a config file located at: `application/config/user_agents.php`. You may add items to the various user agent arrays if needed.

Example

When the User Agent class is initialized it will attempt to determine whether the user agent browsing your site is a web browser, a mobile device, or a robot. It will also gather the platform information if it is available.

```
$this->load->library('user_agent');

if ($this->agent->is_browser())
{
    $agent = $this->agent->browser().' '.$this->agent->version();
}
elseif ($this->agent->is_robot())
{
    $agent = $this->agent->robot();
}
elseif ($this->agent->is_mobile())
{
    $agent = $this->agent->mobile();
}
else
{
    $agent = 'Unidentified User Agent';
}

echo $agent;

echo $this->agent->platform(); // Platform info (Windows, Linux, Mac, etc.)
```

Function Reference

`$this->agent->is_browser()`

Returns TRUE/FALSE (boolean) if the user agent is a known web browser.

```
if ($this->agent->is_browser('Safari'))
{
    echo 'You are using Safari.';
}
elseif ($this->agent->is_browser())
{
    echo 'You are using a browser.';
}
```

: The string “Safari” in this example is an array key in the list of browser definitions. You can find this list in `application/config/user_agents.php` if you want to add new browsers or change the stings.

`$this->agent->is_mobile()`

Returns TRUE/FALSE (boolean) if the user agent is a known mobile device.

```
if ($this->agent->is_mobile('iphone'))
{
    $this->load->view('iphone/home');
}
elseif ($this->agent->is_mobile())
{
    $this->load->view('mobile/home');
}
else
{
    $this->load->view('web/home');
}
```

`$this->agent->is_robot()`

Returns TRUE/FALSE (boolean) if the user agent is a known robot.

: The user agent library only contains the most common robot definitions. It is not a complete list of bots. There are hundreds of them so searching for each one would not be very efficient. If you find that some bots that commonly visit your site are missing from the list you can add them to your `application/config/user_agents.php` file.

`$this->agent->is_referral()`

Returns TRUE/FALSE (boolean) if the user agent was referred from another site.

`$this->agent->browser()`

Returns a string containing the name of the web browser viewing your site.

`$this->agent->version()`

Returns a string containing the version number of the web browser viewing your site.

`$this->agent->mobile()`

Returns a string containing the name of the mobile device viewing your site.

`$this->agent->robot()`

Returns a string containing the name of the robot viewing your site.

`$this->agent->platform()`

Returns a string containing the platform viewing your site (Linux, Windows, OS X, etc.).

`$this->agent->referrer()`

The referrer, if the user agent was referred from another site. Typically you'll test for this as follows:

```
if ($this->agent->is_referral())
{
    echo $this->agent->referrer();
}
```

`$this->agent->agent_string()`

Returns a string containing the full user agent string. Typically it will be something like this:

Mozilla/5.0 (Macintosh; U; Intel Mac OS X; en-US; rv:1.8.0.4) Gecko/20060613 Camino/1.0.2

`$this->agent->accept_lang()`

Lets you determine if the user agent accepts a particular language. Example:

```
if ($this->agent->accept_lang('en'))
{
    echo 'You accept English!';
}
```

: This function is not typically very reliable since some browsers do not provide language info, and even among those that do, it is not always accurate.

`$this->agent->accept_charset()`

Lets you determine if the user agent accepts a particular character set. Example:

```
if ($this->agent->accept_charset('utf-8'))
{
    echo 'You browser supports UTF-8!';
}
```

: This function is not typically very reliable since some browsers do not provide character-set info, and even among those that do, it is not always accurate.

10.13.28 XML-RPC and XML-RPC Server Classes

CodeIgniter's XML-RPC classes permit you to send requests to another server, or set up your own XML-RPC server to receive requests.

What is XML-RPC?

Quite simply it is a way for two computers to communicate over the internet using XML. One computer, which we will call the client, sends an XML-RPC **request** to another computer, which we will call the server. Once the server receives and processes the request it will send back a **response** to the client.

For example, using the MetaWeblog API, an XML-RPC Client (usually a desktop publishing tool) will send a request to an XML-RPC Server running on your site. This request might be a new weblog entry being sent for publication, or it could be a request for an existing entry for editing. When the XML-RPC Server receives this request it will examine it to determine which class/method should be called to process the request. Once processed, the server will then send back a response message.

For detailed specifications, you can visit the [XML-RPC](#) site.

Initializing the Class

Like most other classes in CodeIgniter, the XML-RPC and XML-RPCS classes are initialized in your controller using the `$this->load->library` function:

To load the XML-RPC class you will use:

```
$this->load->library('xmlrpc');
```

Once loaded, the xml-rpc library object will be available using: `$this->xmlrpc`

To load the XML-RPC Server class you will use:

```
$this->load->library('xmlrpc');
$this->load->library('xmlrpcs');
```

Once loaded, the xml-rpcs library object will be available using: `$this->xmlrpcs`

: When using the XML-RPC Server class you must load BOTH the XML-RPC class and the XML-RPC Server class.

Sending XML-RPC Requests

To send a request to an XML-RPC server you must specify the following information:

- The URL of the server
- The method on the server you wish to call
- The *request* data (explained below).

Here is a basic example that sends a simple Weblogs.com ping to the [Ping-o-Matic](#)

```
$this->load->library('xmlrpc');

$this->xmlrpc->server('http://rpc.pingomatic.com/', 80);
$this->xmlrpc->method('weblogUpdates.ping');

$request = array('My Photoblog', 'http://www.my-site.com/photoblog/');
```

```
$this->xmlrpc->request($request);

if ( ! $this->xmlrpc->send_request() )
{
    echo $this->xmlrpc->display_error();
}
```

Explanation The above code initializes the XML-RPC class, sets the server URL and method to be called (we-blogUpdates.ping). The request (in this case, the title and URL of your site) is placed into an array for transportation, and compiled using the request() function. Lastly, the full request is sent. If the send_request() method returns false we will display the error message sent back from the XML-RPC Server.

Anatomy of a Request

An XML-RPC request is simply the data you are sending to the XML-RPC server. Each piece of data in a request is referred to as a request parameter. The above example has two parameters: The URL and title of your site. When the XML-RPC server receives your request, it will look for parameters it requires.

Request parameters must be placed into an array for transportation, and each parameter can be one of seven data types (strings, numbers, dates, etc.). If your parameters are something other than strings you will have to include the data type in the request array.

Here is an example of a simple array with three parameters:

```
$request = array('John', 'Doe', 'www.some-site.com');
$this->xmlrpc->request($request);
```

If you use data types other than strings, or if you have several different data types, you will place each parameter into its own array, with the data type in the second position:

```
$request = array (
    array('John', 'string'),
    array('Doe', 'string'),
    array(FALSE, 'boolean'),
    array(12345, 'int')
);
$this->xmlrpc->request($request);
```

The Data Types section below has a full list of data types. Creating an XML-RPC Server
=====

An XML-RPC Server acts as a traffic cop of sorts, waiting for incoming requests and redirecting them to the appropriate functions for processing.

To create your own XML-RPC server involves initializing the XML-RPC Server class in your controller where you expect the incoming request to appear, then setting up an array with mapping instructions so that incoming requests can be sent to the appropriate class and method for processing.

Here is an example to illustrate:

```
$this->load->library('xmlrpc');
$this->load->library('xmlrpcs');

$config['functions']['new_post'] = array('function' => 'My_blog.new_entry'),
$config['functions']['update_post'] = array('function' => 'My_blog.update_entry');
$config['object'] = $this;
```

```
$this->xmlrpcs->initialize($config);
$this->xmlrpcs->serve();
```

The above example contains an array specifying two method requests that the Server allows. The allowed methods are on the left side of the array. When either of those are received, they will be mapped to the class and method on the right.

The ‘object’ key is a special key that you pass an instantiated class object with, which is necessary when the method you are mapping to is not part of the CodeIgniter super object.

In other words, if an XML-RPC Client sends a request for the `new_post` method, your server will load the `My_blog` class and call the `new_entry` function. If the request is for the `update_post` method, your server will load the `My_blog` class and call the `update_entry` function.

The function names in the above example are arbitrary. You’ll decide what they should be called on your server, or if you are using standardized APIs, like the Blogger or MetaWeblog API, you’ll use their function names.

There are two additional configuration keys you may make use of when initializing the server class: `debug` can be set to `TRUE` in order to enable debugging, and `xss_clean` may be set to `FALSE` to prevent sending data through the Security library’s `xss_clean` function.

Processing Server Requests

When the XML-RPC Server receives a request and loads the class/method for processing, it will pass an object to that method containing the data sent by the client.

Using the above example, if the `new_post` method is requested, the server will expect a class to exist with this prototype:

```
class My_blog extends CI_Controller {

    public function new_post($request)
    {

    }

}
```

The `$request` variable is an object compiled by the Server, which contains the data sent by the XML-RPC Client. Using this object you will have access to the *request parameters* enabling you to process the request. When you are done you will send a Response back to the Client.

Below is a real-world example, using the Blogger API. One of the methods in the Blogger API is `getUserInfo()`. Using this method, an XML-RPC Client can send the Server a username and password, in return the Server sends back information about that particular user (nickname, user ID, email address, etc.). Here is how the processing function might look:

```
class My_blog extends CI_Controller {

    function getUserInfo($request)
    {
        $username = 'smitty';
        $password = 'secretsmittypass';

        $this->load->library('xmlrpc');

        $parameters = $request->output_parameters();

        if ($parameters['1'] != $username AND $parameters['2'] != $password)
```

```
{
    return $this->xmlrpc->send_error_message('100', 'Invalid Access');
}

$response = array(array('nickname' => array('Smitty','string'),
                        'userid'   => array('99','string'),
                        'url'      => array('http://yoursite.com','string'),
                        'email'    => array('jsmith@yoursite.com','string'),
                        'lastname' => array('Smith','string'),
                        'firstname' => array('John','string')
                    ),
                  'struct');

return $this->xmlrpc->send_response($response);
}
```

Notes: The `output_parameters()` function retrieves an indexed array corresponding to the request parameters sent by the client. In the above example, the output parameters will be the username and password.

If the username and password sent by the client were not valid, and error message is returned using `send_error_message()`.

If the operation was successful, the client will be sent back a response array containing the user's info.

Formatting a Response

Similar to *Requests*, *Responses* must be formatted as an array. However, unlike requests, a response is an array **that contains a single item**. This item can be an array with several additional arrays, but there can be only one primary array index. In other words, the basic prototype is this:

```
$response = array('Response data', 'array');
```

Responses, however, usually contain multiple pieces of information. In order to accomplish this we must put the response into its own array so that the primary array continues to contain a single piece of data. Here's an example showing how this might be accomplished:

```
$response = array (
    array(
        'first_name' => array('John', 'string'),
        'last_name'  => array('Doe', 'string'),
        'member_id'  => array(123435, 'int'),
        'todo_list'  => array(array('clean house', 'call mom', 'water plants'), 'array')
    ),
    'struct'
);
```

Notice that the above array is formatted as a struct. This is the most common data type for responses.

As with Requests, a response can be one of the seven data types listed in the Data Types section.

Sending an Error Response

If you need to send the client an error response you will use the following:

```
return $this->xmlrpc->send_error_message('123', 'Requested data not available');
```

The first parameter is the error number while the second parameter is the error message.

Creating Your Own Client and Server

To help you understand everything we've covered thus far, let's create a couple controllers that act as XML-RPC Client and Server. You'll use the Client to send a request to the Server and receive a response.

The Client Using a text editor, create a controller called `Xmlrpc_client.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Xmlrpc_client extends CI_Controller {

    public function index()
    {
        $this->load->helper('url');
        $server_url = site_url('xmlrpc_server');

        $this->load->library('xmlrpc');

        $this->xmlrpc->server($server_url, 80);
        $this->xmlrpc->method('Greetings');

        $request = array('How is it going?');
        $this->xmlrpc->request($request);

        if ( ! $this->xmlrpc->send_request() )
        {
            echo $this->xmlrpc->display_error();
        }
        else
        {
            echo '<pre>';
            print_r($this->xmlrpc->display_response());
            echo '</pre>';
        }
    }
}

?>
```

: In the above code we are using a “url helper”. You can find more information in the *Helpers Functions* page.

The Server Using a text editor, create a controller called `Xmlrpc_server.php`. In it, place this code and save it to your `application/controllers/` folder:

```
<?php

class Xmlrpc_server extends CI_Controller {

    public function index()
    {
```

```
$this->load->library('xmlrpc');
$this->load->library('xmlrpcs');

$config['functions']['Greetings'] = array('function' => 'Xmlrpc_server.process');

$this->xmlrpcs->initialize($config);
$this->xmlrpcs->serve();
}

public function process($request)
{
    $parameters = $request->output_parameters();

    $response = array(
        array(
            'you_said' => $parameters[0],
            'i_respond' => 'Not bad at all.'
        ),
        'struct'
    );

    return $this->xmlrpc->send_response($response);
}
?>
```

Try it! Now visit the your site using a URL similar to this:

`example.com/index.php/xmlrpc_client/`

You should now see the message you sent to the server, and its response back to you.

The client you created sends a message (“How’s is going?”) to the server, along with a request for the “Greetings” method. The Server receives the request and maps it to the “process” function, where a response is sent back.

Using Associative Arrays In a Request Parameter

If you wish to use an associative array in your method parameters you will need to use a struct datatype:

```
$request = array(
    array(
        // Param 0
        array(
            'name'=>'John'
        ),
        'struct'
    ),
    array(
        // Param 1
        array(
            'size'=>'large',
            'shape'=>'round'
        ),
        'struct'
    )
)
```

```
);
$this->xmlrpc->request($request);
```

You can retrieve the associative array when processing the request in the Server.

```
$parameters = $request->output_parameters();
$name = $parameters[0]['name'];
$size = $parameters[1]['size'];
$shape = $parameters[1]['shape'];
```

XML-RPC Function Reference

`$this->xmlrpc->server()`

Sets the URL and port number of the server to which a request is to be sent:

```
$this->xmlrpc->server('http://www.sometimes.com/pings.php', 80);
```

`$this->xmlrpc->timeout()`

Set a time out period (in seconds) after which the request will be canceled:

```
$this->xmlrpc->timeout(6);
```

`$this->xmlrpc->method()`

Sets the method that will be requested from the XML-RPC server:

```
$this->xmlrpc->method('method');
```

Where method is the name of the method.

`$this->xmlrpc->request()`

Takes an array of data and builds request to be sent to XML-RPC server:

```
$request = array(array('My Photoblog', 'string'), 'http://www.yoursite.com/photoblog/');
$this->xmlrpc->request($request);
```

`$this->xmlrpc->send_request()`

The request sending function. Returns boolean TRUE or FALSE based on success for failure, enabling it to be used conditionally.

`$this->xmlrpc->set_debug(TRUE);`

Enables debugging, which will display a variety of information and error data helpful during development.

`$this->xmlrpc->display_error()`

Returns an error message as a string if your request failed for some reason.

```
echo $this->xmlrpc->display_error();
```

`$this->xmlrpc->display_response()`

Returns the response from the remote server once request is received. The response will typically be an associative array.

```
$this->xmlrpc->display_response();
```

`$this->xmlrpc->send_error_message()`

This function lets you send an error message from your server to the client. First parameter is the error number while the second parameter is the error message.

```
return $this->xmlrpc->send_error_message('123', 'Requested data not available');
```

`$this->xmlrpc->send_response()`

Lets you send the response from your server to the client. An array of valid data values must be sent with this method.

```
$response = array(
    array(
        'flerror' => array(FALSE, 'boolean'),
        'message' => "Thanks for the ping!"
    )
    'struct');
return $this->xmlrpc->send_response($response);
```

Data Types

According to the [XML-RPC spec](#) there are seven types of values that you can send via XML-RPC:

- *int* or *i4*
- *boolean*
- *string*
- *double*
- *dateTime.iso8601*
- *base64*
- *struct* (contains array of values)
- *array* (contains array of values)

10.13.29 Zip Encoding Class

CodeIgniter's Zip Encoding Class classes permit you to create Zip archives. Archives can be downloaded to your desktop or saved to a directory.

Initializing the Class

Like most other classes in CodeIgniter, the Zip class is initialized in your controller using the `$this->load->library` function:

```
$this->load->library('zip');
```

Once loaded, the Zip library object will be available using: `$this->zip`

Usage Example

This example demonstrates how to compress a file, save it to a folder on your server, and download it to your desktop.

```
$name = 'mydata1.txt';
$data = 'A Data String!';

$this->zip->add_data($name, $data);

// Write the zip file to a folder on your server. Name it "my_backup.zip"
$this->zip->archive('/path/to/directory/my_backup.zip');

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

Function Reference

`$this->zip->add_data()`

Permits you to add data to the Zip archive. The first parameter must contain the name you would like given to the file, the second parameter must contain the file data as a string:

```
$name = 'my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);
```

You are allowed multiple calls to this function in order to add several files to your archive. Example:

```
$name = 'mydata1.txt';
$data = 'A Data String!';
$this->zip->add_data($name, $data);

$name = 'mydata2.txt';
$data = 'Another Data String!';
$this->zip->add_data($name, $data);
```

Or you can pass multiple files using an array:

```
$data = array(
    'mydata1.txt' => 'A Data String!',
    'mydata2.txt' => 'Another Data String!'
);

$this->zip->add_data($data);

$this->zip->download('my_backup.zip');
```

If you would like your compressed data organized into sub-folders, include the path as part of the filename:

```
$name = 'personal/my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);
```

The above example will place my_bio.txt inside a folder called personal.

\$this->zip->add_dir()

Permits you to add a directory. Usually this function is unnecessary since you can place your data into folders when using `$this->zip->add_data()`, but if you would like to create an empty folder you can do so. Example:

```
$this->zip->add_dir('myfolder'); // Creates a folder called "myfolder"
```

\$this->zip->read_file()

Permits you to compress a file that already exists somewhere on your server. Supply a file path and the zip class will read it and add it to the archive:

```
$path = '/path/to/photo.jpg';

$this->zip->read_file($path);

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

If you would like the Zip archive to maintain the directory structure of the file in it, pass TRUE (boolean) in the second parameter. Example:

```
$path = '/path/to/photo.jpg';

$this->zip->read_file($path, TRUE);

// Download the file to your desktop. Name it "my_backup.zip"
$this->zip->download('my_backup.zip');
```

In the above example, photo.jpg will be placed inside two folders: path/to/

\$this->zip->read_dir()

Permits you to compress a folder (and its contents) that already exists somewhere on your server. Supply a file path to the directory and the zip class will recursively read it and recreate it as a Zip archive. All files contained within the supplied path will be encoded, as will any sub-folders contained within it. Example:

```
$path = '/path/to/your/directory/';  
  
$this->zip->read_dir($path);  
  
// Download the file to your desktop. Name it "my_backup.zip"  
$this->zip->download('my_backup.zip');
```

By default the Zip archive will place all directories listed in the first parameter inside the zip. If you want the tree preceding the target folder to be ignored you can pass FALSE (boolean) in the second parameter. Example:

```
$path = '/path/to/your/directory/';  
  
$this->zip->read_dir($path, FALSE);
```

This will create a ZIP with the folder “directory” inside, then all sub-folders stored correctly inside that, but will not include the folders /path/to/your.

\$this->zip->archive()

Writes the Zip-encoded file to a directory on your server. Submit a valid server path ending in the file name. Make sure the directory is writable (666 or 777 is usually OK). Example:

```
$this->zip->archive('/path/to/folder/myarchive.zip'); // Creates a file named myarchive.zip
```

\$this->zip->download()

Causes the Zip file to be downloaded from your server. The function must be passed the name you would like the zip file called. Example:

```
$this->zip->download('latest_stuff.zip'); // File will be named "latest_stuff.zip"
```

: Do not display any data in the controller in which you call this function since it sends various server headers that cause the download to happen and the file to be treated as binary.

\$this->zip->get_zip()

Returns the Zip-compressed file data. Generally you will not need this function unless you want to do something unique with the data. Example:

```
$name = 'my_bio.txt';  
$data = 'I was born in an elevator...';  
  
$this->zip->add_data($name, $data);  
  
$zip_file = $this->zip->get_zip();
```

\$this->zip->clear_data()

The Zip class caches your zip data so that it doesn't need to recompile the Zip archive for each function you use above. If, however, you need to create multiple Zips, each with different data, you can clear the cache between calls. Example:

```
$name = 'my_bio.txt';
$data = 'I was born in an elevator...';

$this->zip->add_data($name, $data);
$zip_file = $this->zip->get_zip();

$this->zip->clear_data();

$name = 'photo.jpg';
$this->zip->read_file("/path/to/photo.jpg"); // Read the file's contents

$this->zip->download('myphotos.zip');
```

10.14 Helpers

10.14.1 Array Helper

The Array Helper file contains functions that assist in working with arrays.

Page Contents

- Array Helper
 - Loading this Helper
 - `element()`
 - `elements()`
 - `random_element()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('array');
```

The following functions are available:

`element()`

element (*\$item*, *\$array*, *\$default* = *NULL*)

- **\$item** (*string*) – Item to fetch from the array
- **\$array** (*array*) – Input array
- **\$default** (*bool*) – What to return if the array isn't valid

NULL on failure or the array item.

Lets you fetch an item from an array. The function tests whether the array index is set and whether it has a value. If a value exists it is returned. If a value does not exist it returns NULL, or whatever you've specified as the default value via the third parameter.

Example:

```
$array = array(
    'color' => 'red',
    'shape' => 'round',
    'size'  => ''
);

echo element('color', $array); // returns "red"
echo element('size', $array, 'foobar'); // returns "foobar"
```

elements()

elements (*\$items*, *\$array*, *\$default = NULL*)

- **\$item** (*string*) – Item to fetch from the array
- **\$array** (*array*) – Input array
- **\$default** (*bool*) – What to return if the array isn't valid

NULL on failure or the array item.

Lets you fetch a number of items from an array. The function tests whether each of the array indices is set. If an index does not exist it is set to NULL, or whatever you've specified as the default value via the third parameter.

Example:

```
$array = array(
    'color' => 'red',
    'shape' => 'round',
    'radius' => '10',
    'diameter' => '20'
);

$my_shape = elements(array('color', 'shape', 'height'), $array);
```

The above will return the following array:

```
array(
    'color' => 'red',
    'shape' => 'round',
    'height' => NULL
);
```

You can set the third parameter to any default value you like.

```
$my_shape = elements(array('color', 'shape', 'height'), $array, 'foobar');
```

The above will return the following array:

```
array(
    'color'      => 'red',
    'shape'      => 'round',
    'height'     => 'foobar'
);
```

This is useful when sending the `$_POST` array to one of your Models. This prevents users from sending additional POST data to be entered into your tables.

```
$this->load->model('post_model');
$this->post_model->update(
    elements(array('id', 'title', 'content'), $_POST)
);
```

This ensures that only the id, title and content fields are sent to be updated.

random_element()

random_element (\$array)

- **\$array** (*array*) – Input array
- string (a random element from the array)

Takes an array as input and returns a random element from it.

Usage example:

```
$quotes = array(
    "I find that the harder I work, the more luck I seem to have. - Thomas Jefferson",
    "Don't stay in bed, unless you can make money in bed. - George Burns",
    "We didn't lose the game; we just ran out of time. - Vince Lombardi",
    "If everything seems under control, you're not going fast enough. - Mario Andretti",
    "Reality is merely an illusion, albeit a very persistent one. - Albert Einstein",
    "Chance favors the prepared mind - Louis Pasteur"
);

echo random_element($quotes);
```

10.14.2 CAPTCHA Helper

The CAPTCHA Helper file contains functions that assist in creating CAPTCHA images.

Page Contents

- CAPTCHA Helper
 - Loading this Helper
 - create_captcha()
 - * Using the CAPTCHA helper
 - * Adding a Database

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('captcha');
```

The following functions are available:

create_captcha()

```
function create_captcha($data = '', $img_path = '', $img_url = '', $font_path = '')
```

- **\$data** (*array*) – Array of data for the CAPTCHA
- **\$img_path** (*string*) – Path to create the image in
- **\$img_url** (*string*) – URL to the CAPTCHA image folder
- **\$font_path** (*string*) – Server path to font

array

Takes an array of information to generate the CAPTCHA as input and creates the image to your specifications, returning an array of associative data about the image.

```
array(
    'word'      => CAPTCHA WORD,
    'time'      => TIMESTAMP (in microtime),
    'image'     => IMAGE TAG,
    'filename'  => IMAGE FILE NAME
)
```

The **image** is the actual image tag:

```

```

The **time** is the micro timestamp used as the image name without the file extension. It will be a number like this: 1139612155.3422

The **word** is the word that appears in the captcha image, which if not supplied to the function, will be a random string.

Using the CAPTCHA helper

Once loaded you can generate a captcha like this:

```
$vals = array(
    'word'      => 'Random word',
    'img_path'  => './captcha/',
    'img_url'   => 'http://example.com/captcha/',
    'font_path' => './path/to/fonts/texb.ttf',
    'img_width' => '150',
    'img_height' => 30,
    'expiration' => 7200,
    'word_length' => 8,
    'pool'      => '0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOPQRSTUVWXYZ',

    // White background and border, black text and red grid
    'colors'    => array(
        'background' => array(255, 255, 255),
        'border'    => array(255, 255, 255),
        'text'      => array(0, 0, 0),
        'grid'      => array(255, 40, 40)
    )
);

$cap = create_captcha($vals);
echo $cap['image'];
```

- The captcha function requires the GD image library.
- Only the **img_path** and **img_url** are required.
- If a **word** is not supplied, the function will generate a random ASCII string. You might put together your own word library that you can draw randomly from.
- If you do not specify a path to a TRUE TYPE font, the native ugly GD font will be used.
- The “captcha” folder must be writable (666, or 777)
- The **expiration** (in seconds) signifies how long an image will remain in the captcha folder before it will be deleted. The default is two hours.
- **word_length** defaults to 8, **pool** defaults to ‘0123456789abcdefghijklmnopqrstuvwxyzABCDEFGHIJKLMNOSTUVWXYZ’
- If any of the **colors** values is missing, it will be replaced by the default.

Adding a Database

In order for the captcha function to prevent someone from submitting, you will need to add the information returned from `create_captcha()` to your database. Then, when the data from the form is submitted by the user you will need to verify that the data exists in the database and has not expired.

Here is a table prototype:

```
CREATE TABLE captcha (  
    captcha_id bigint(13) unsigned NOT NULL auto_increment,  
    captcha_time int(10) unsigned NOT NULL,  
    ip_address varchar(45) NOT NULL,  
    word varchar(20) NOT NULL,  
    PRIMARY KEY `captcha_id` (`captcha_id`),  
    KEY `word` (`word`)  
);
```

Here is an example of usage with a database. On the page where the CAPTCHA will be shown you’ll have something like this:

```
$this->load->helper('captcha');  
$vals = array(  
    'img_path'      => './captcha/',  
    'img_url'       => 'http://example.com/captcha/'  
);  
  
$cap = create_captcha($vals);  
$data = array(  
    'captcha_time'  => $cap['time'],  
    'ip_address'    => $this->input->ip_address(),  
    'word'          => $cap['word']  
);  
  
$query = $this->db->insert_string('captcha', $data);  
$this->db->query($query);  
  
echo 'Submit the word you see below:';  
echo $cap['image'];  
echo '<input type="text" name="captcha" value="" />';
```

Then, on the page that accepts the submission you’ll have something like this:

```
// First, delete old captchas
$expiration = time() - 7200; // Two hour limit
$this->db->where('captcha_time < ', $expiration)
    ->delete('captcha');

// Then see if a captcha exists:
$sql = 'SELECT COUNT(*) AS count FROM captcha WHERE word = ? AND ip_address = ? AND captcha_time > ?';
$binds = array($_POST['captcha'], $this->input->ip_address(), $expiration);
$query = $this->db->query($sql, $binds);
$row = $query->row();

if ($row->count == 0)
{
    echo 'You must submit the word that appears in the image.';
}
```

10.14.3 Cookie Helper

The Cookie Helper file contains functions that assist in working with cookies.

Page Contents

- Cookie Helper
 - Loading this Helper
 - set_cookie()
 - get_cookie()
 - delete_cookie()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('cookie');
```

The following functions are available:

set_cookie()

```
set_cookie ($name = '', $value = '', $expire = '', $domain = '', $path = '/', $prefix = '', $secure = FALSE,
    $httponly = FALSE)
```

- **\$name** (*string*) – Cookie name
- **\$value** (*string*) – Cookie value
- **\$expire** (*int*) – Number of seconds until expiration
- **\$domain** (*string*) – Cookie domain (usually: .yourdomain.com)
- **\$path** (*string*) – Cookie path
- **\$prefix** (*string*) – Cookie name prefix
- **\$secure** (*bool*) – Whether to only send the cookie through HTTPS

- **\$httponly** (*bool*) – Whether to hide the cookie from JavaScript

void

This helper function gives you view file friendly syntax to set browser cookies. Refer to the *Input Library* for a description of its use, as this function is an alias for `CI_Input::set_cookie()`.

get_cookie()

get_cookie (*\$index = ''*, *\$xss_clean = FALSE*)

- **\$index** (*string*) – Cookie name
- **\$xss_clean** (*bool*) – Whether to apply XSS filtering to the returned value

mixed

This helper function gives you view file friendly syntax to get browser cookies. Refer to the *Input Library* for a description of its use, as this function is an alias for `CI_Input::cookie()`.

delete_cookie()

delete_cookie (*\$name = ''*, *\$domain = ''*, *\$path = '/'*, *\$prefix = ''*)

- **\$name** (*string*) – Cookie name
- **\$domain** (*string*) – Cookie domain (usually: `.yourdomain.com`)
- **\$path** (*string*) – Cookie path
- **\$prefix** (*string*) – Cookie name prefix

void

Lets you delete a cookie. Unless you've set a custom path or other values, only the name of the cookie is needed.

```
delete_cookie('name');
```

This function is otherwise identical to `set_cookie()`, except that it does not have the value and expiration parameters. You can submit an array of values in the first parameter or you can set discrete parameters.

```
delete_cookie($name, $domain, $path, $prefix)
```

10.14.4 Date Helper

The Date Helper file contains functions that help you work with dates.

Page Contents

- Date Helper
 - Loading this Helper
 - now()
 - mdate()
 - standard_date()
 - * Supported formats
 - local_to_gmt()
 - gmt_to_local()
 - mysql_to_unix()
 - unix_to_human()
 - human_to_unix()
 - nice_date()
 - timespan()
 - days_in_month()
 - date_range()
 - timezones()
 - timezone_menu()
 - Timezone Reference

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('date');
```

The following functions are available:

now()

```
now ($timezone = NULL)
```

- **\$timezone** (*string*) – Timezone

int

Returns the current time as a UNIX timestamp, referenced either to your server's local time or any PHP supported timezone, based on the “time reference” setting in your config file. If you do not intend to set your master time reference to any other PHP supported timezone (which you'll typically do if you run a site that lets each user set their own timezone settings) there is no benefit to using this function over PHP's `time()` function.

```
echo now('Australia/Victoria');
```

If a timezone is not provided, it will return `time()` based on the **time_reference** setting.

mdate()

```
mdate ($datestr = '', $time = '')
```

- **\$datestr** (*string*) – Date string

- **\$time** (*int*) – UNIX timestamp

int

This function is identical to PHP's [date\(\)](#) function, except that it lets you use MySQL style date codes, where each code letter is preceded with a percent sign, e.g. `%Y %m %d`

The benefit of doing dates this way is that you don't have to worry about escaping any characters that are not date codes, as you would normally have to do with the `date()` function.

Example:

```
$datestring = 'Year: %Y Month: %m Day: %d - %h:%i %a';
$time = time();
echo mdate($datestring, $time);
```

If a timestamp is not included in the second parameter the current time will be used.

standard_date()

standard_date (*\$fmt* = 'DATE_RFC822', *\$time* = NULL)

- **\$fmt** (*string*) – Date format
- **\$time** (*int*) – UNIX timestamp

string

Lets you generate a date string in one of several standardized formats.

Example:

```
$format = 'DATE_RFC822';
$time = time();
echo standard_date($format, $time);
```

: This function is DEPRECATED. Use the native `date()` combined with [DateTime's format constants](#) instead:

```
echo date(DATE_RFC822, time());
```

Supported formats

Constant	Description	Example
DATE_ATOM	Atom	2005-08-15T16:13:03+0000
DATE_COOKIE	HTTP Cookies	Sun, 14 Aug 2005 16:13:03 UTC
DATE_ISO8601	ISO-8601	2005-08-14T16:13:03+00:00
DATE_RFC822	RFC 822	Sun, 14 Aug 05 16:13:03 UTC
DATE_RFC850	RFC 850	Sunday, 14-Aug-05 16:13:03 UTC
DATE_RFC1036	RFC 1036	Sunday, 14-Aug-05 16:13:03 UTC
DATE_RFC1123	RFC 1123	Sun, 14 Aug 2005 16:13:03 UTC
DATE_RFC2822	RFC 2822	Sun, 14 Aug 2005 16:13:03 +0000
DATE_RSS	RSS	Sun, 14 Aug 2005 16:13:03 UTC
DATE_W3C	W3C	2005-08-14T16:13:03+0000

local_to_gmt()

local_to_gmt (*\$time* = '')

- **\$time** (*int*) – UNIX timestamp

string

Takes a UNIX timestamp as input and returns it as GMT.

Example:

```
$gmt = local_to_gmt(time());
```

gmt_to_local()

gmt_to_local (*\$time* = '', *\$timezone* = 'UTC', *\$dst* = FALSE)

- **\$time** (*int*) – UNIX timestamp
- **\$timezone** (*string*) – Timezone
- **\$dst** (*bool*) – Whether DST is active

int

Takes a UNIX timestamp (referenced to GMT) as input, and converts it to a localized timestamp based on the timezone and Daylight Saving Time submitted.

Example:

```
$timestamp = 1140153693;
$timezone = 'UM8';
$daylight_saving = TRUE;
echo gmt_to_local($timestamp, $timezone, $daylight_saving);
```

: For a list of timezones see the reference at the bottom of this page.

mysql_to_unix()

mysql_to_unix (*\$time* = '')

- **\$time** (*int*) – UNIX timestamp

int

Takes a MySQL Timestamp as input and returns it as a UNIX timestamp.

Example:

```
$unix = mysql_to_unix('20061124092345');
```

unix_to_human()

unix_to_human (*\$time* = '', *\$seconds* = FALSE, *\$fmt* = 'us')

- **\$time** (*int*) – UNIX timestamp
- **\$seconds** (*bool*) – Whether to show seconds
- **\$fmt** (*string*) – format (us or euro)

integer

Takes a UNIX timestamp as input and returns it in a human readable format with this prototype:

```
YYYY-MM-DD HH:MM:SS AM/PM
```

This can be useful if you need to display a date in a form field for submission.

The time can be formatted with or without seconds, and it can be set to European or US format. If only the timestamp is submitted it will return the time without seconds formatted for the U.S.

Examples:

```
$now = time();  
echo unix_to_human($now); // U.S. time, no seconds  
echo unix_to_human($now, TRUE, 'us'); // U.S. time with seconds  
echo unix_to_human($now, TRUE, 'eu'); // Euro time with seconds
```

human_to_unix()

human_to_unix (*\$datestr* = '')

- **\$datestr** (*int*) – Date string

int UNIX timestamp or FALSE on failure

The opposite of the `unix_to_time()` function. Takes a “human” time as input and returns it as a UNIX timestamp. This is useful if you accept “human” formatted dates submitted via a form. Returns boolean FALSE date string passed to it is not formatted as indicated above.

Example:

```
$now = time();
$human = unix_to_human($now);
$unix = human_to_unix($human);
```

nice_date()

nice_date (*\$bad_date* = '', *\$format* = FALSE)

- **\$bad_date** (*int*) – The terribly formatted date-like string
- **\$format** (*string*) – Date format to return (same as PHP's `date()` function)

string

This function can take a number poorly-formed date formats and convert them into something useful. It also accepts well-formed dates.

The function will return a UNIX timestamp by default. You can, optionally, pass a format string (the same type as the PHP `date()` function accepts) as the second parameter.

Example:

```
$bad_date = '199605';
// Should Produce: 1996-05-01
$better_date = nice_date($bad_date, 'Y-m-d');

$bad_date = '9-11-2001';
// Should Produce: 2001-09-11
$better_date = nice_date($bad_date, 'Y-m-d');
```

timespan()

timespan (*\$seconds* = 1, *\$time* = '', *\$units* = '')

- **\$seconds** (*int*) – Number of seconds
- **\$time** (*string*) – UNIX timestamp
- **\$units** (*int*) – Number of time units to display

string

Formats a UNIX timestamp so that it appears similar to this:

```
1 Year, 10 Months, 2 Weeks, 5 Days, 10 Hours, 16 Minutes
```

The first parameter must contain a UNIX timestamp. The second parameter must contain a timestamp that is greater than the first timestamp. The third parameter is optional and limits the number of time units to display.

If the second parameter empty, the current time will be used.

The most common purpose for this function is to show how much time has elapsed from some point in time in the past to now.

Example:

```
$post_date = '1079621429';
$now = time();
$units = 2;
echo timespan($post_date, $now, $units);
```

: The text generated by this function is found in the following language file: *language/<your_lang>/date_lang.php*

days_in_month()

days_in_month (*\$month* = 0, *\$year* = '')

- **\$month** (*int*) – a numeric month
- **\$year** (*int*) – a numeric year

int

Returns the number of days in a given month/year. Takes leap years into account.

Example:

```
echo days_in_month(06, 2005);
```

If the second parameter is empty, the current year will be used.

date_range()

date_range (*\$unix_start* = '', *\$mixed* = '', *\$is_unix* = TRUE, *\$format* = 'Y-m-d')

- **\$unix_start** (*int*) – UNIX timestamp of the range start date
- **\$mixed** (*int*) – UNIX timestamp of the range end date or interval in days
- **\$is_unix** (*bool*) – set to FALSE if \$mixed is not a timestamp
- **\$format** (*string*) – Output date format, same as in `date()`

array

Returns a list of dates within a specified period.

Example:

```
$range = date_range('2012-01-01', '2012-01-15');
echo "First 15 days of 2012:";
foreach ($range as $date)
{
    echo $date."\n";
}
```

timezones()

timezones (*\$tz* = '')

- **\$tz** (*string*) – a numeric timezone

string

Takes a timezone reference (for a list of valid timezones, see the “Timezone Reference” below) and returns the number of hours offset from UTC.

Example:

```
echo timezones('UM5');
```

This function is useful when used with `timezone_menu()`.

timezone_menu()

timezone_menu (*\$default* = 'UTC', *\$class* = '', *\$name* = 'timezones', *\$attributes* = '')

- **\$default** (*string*) – Timezone
- **\$class** (*string*) – Class name
- **\$name** (*string*) – Menu name
- **\$attributes** (*mixed*) – HTML attributes

string

Generates a pull-down menu of timezones, like this one:

This menu is useful if you run a membership site in which your users are allowed to set their local timezone value.

The first parameter lets you set the “selected” state of the menu. For example, to set Pacific time as the default you will do this:

```
echo timezone_menu('UM8');
```

Please see the timezone reference below to see the values of this menu.

The second parameter lets you set a CSS class name for the menu.

The fourth parameter lets you set one or more attributes on the generated select tag.

: The text contained in the menu is found in the following language file: *language/<your_lang>/date_lang.php*

Timezone Reference

The following table indicates each timezone and its location.

Note some of the location lists have been abridged for clarity and formatting.

	Time Zone	Location
UM12	(UTC - 12:00)	Baker/Howland Island
UM11	(UTC - 11:00)	Samoa Time Zone, Niue
UM10	(UTC - 10:00)	Hawaii-Aleutian Standard Time, Cook Islands
UM95	(UTC - 09:30)	Marquesas Islands
UM9	(UTC - 09:00)	Alaska Standard Time, Gambier Islands
UM8	(UTC - 08:00)	Pacific Standard Time, Clipperton Island
UM7	(UTC - 11:00)	Mountain Standard Time

Continued on next page

Table 10.1 – continued from previous page

Time Zone	Location
UM6	(UTC - 06:00) Central Standard Time
UM5	(UTC - 05:00) Eastern Standard Time, Western Caribbean
UM45	(UTC - 04:30) Venezuelan Standard Time
UM4	(UTC - 04:00) Atlantic Standard Time, Eastern Caribbean
UM35	(UTC - 03:30) Newfoundland Standard Time
UM3	(UTC - 03:00) Argentina, Brazil, French Guiana, Uruguay
UM2	(UTC - 02:00) South Georgia/South Sandwich Islands
UM1	(UTC - 1:00) Azores, Cape Verde Islands
UTC	(UTC) Greenwich Mean Time, Western European Time
UP1	(UTC +1:00) Central European Time, West Africa Time
UP2	(UTC +2:00) Central Africa Time, Eastern European Time
UP3	(UTC +3:00) Moscow Time, East Africa Time
UP35	(UTC +3:30) Iran Standard Time
UP4	(UTC +4:00) Azerbaijan Standard Time, Samara Time
UP45	(UTC +4:30) Afghanistan
UP5	(UTC +5:00) Pakistan Standard Time, Yekaterinburg Time
UP55	(UTC +5:30) Indian Standard Time, Sri Lanka Time
UP575	(UTC +5:45) Nepal Time
UP6	(UTC +6:00) Bangladesh Standard Time, Bhutan Time, Omsk Time
UP65	(UTC +6:30) Cocos Islands, Myanmar

10.14.5 Directory Helper

The Directory Helper file contains functions that assist in working with directories.

Page Contents

- Directory Helper
 - Loading this Helper
 - `directory_map()`

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('directory');
```

The following functions are available:

directory_map()

This function reads the directory path specified in the first parameter and builds an array representation of it and all its contained files.

```
directory_map($source_dir[, $directory_depth = 0[, $hidden = FALSE]])
```

- **\$source_dir** (*string*) – path to the source directory
- **\$directory_depth** (*integer*) – depth of directories to traverse (0 = fully recursive, 1 = current dir, etc)
- **\$hidden** (*boolean*) – whether to include hidden directories

Examples:

```
$map = directory_map('./mydirectory/');
```

: Paths are almost always relative to your main index.php file.

Sub-folders contained within the directory will be mapped as well. If you wish to control the recursion depth, you can do so using the second parameter (integer). A depth of 1 will only map the top level directory:

```
$map = directory_map('./mydirectory/', 1);
```

By default, hidden files will not be included in the returned array. To override this behavior, you may set a third parameter to true (boolean):

```
$map = directory_map('./mydirectory/', FALSE, TRUE);
```

Each folder name will be an array index, while its contained files will be numerically indexed. Here is an example of a typical array:

```
Array (
    [libraries] => Array
        (
            [0] => benchmark.html
            [1] => config.html
            ["database/"] => Array
                (
                    [0] => query_builder.html
                    [1] => binds.html
                    [2] => configuration.html
                    [3] => connecting.html
                    [4] => examples.html
                    [5] => fields.html
                    [6] => index.html
                    [7] => queries.html
                )
            [2] => email.html
            [3] => file_uploading.html
            [4] => image_lib.html
            [5] => input.html
        )
)
```

```
[6] => language.html
[7] => loader.html
[8] => pagination.html
[9] => uri.html
)
```

10.14.6 Download Helper

The Download Helper lets you download data to your desktop.

Page Contents

- Download Helper
 - Loading this Helper
 - force_download()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('download');
```

The following functions are available:

force_download()

```
force_download($filename = '', $data = '', $set_mime = FALSE)
```

- **\$filename** (*string*) – Filename
- **\$data** (*mixed*) – File contents
- **\$set_mime** (*bool*) – Whether to try to send the actual MIME type

void

Generates server headers which force data to be downloaded to your desktop. Useful with file downloads. The first parameter is the **name you want the downloaded file to be named**, the second parameter is the file data.

If you set the second parameter to NULL and \$filename is an existing, readable file path, then its content will be read instead.

If you set the third parameter to boolean TRUE, then the actual file MIME type (based on the filename extension) will be sent, so that if your browser has a handler for that type - it can use it.

Example:

```
$data = 'Here is some text!';
$name = 'mytext.txt';
force_download($name, $data);
```

If you want to download an existing file from your server you'll need to do the following:

```
// Contents of photo.jpg will be automatically read
force_download('/path/to/photo.jpg', NULL);
```

10.14.7 Email Helper

The Email Helper provides some assistive functions for working with Email. For a more robust email solution, see CodeIgniter's *Email Class*.

Page Contents

- Email Helper
 - Loading this Helper
 - `valid_email()`
 - `send_email()`

: The Email helper is DEPRECATED.

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('email');
```

The following functions are available:

`valid_email()`

`valid_email` (*\$email*)

- **`$email`** (*string*) – Email address

bool

Checks if the input is a correctly formatted e-mail address. Note that it doesn't actually prove that the address will be able to receive mail, but simply that it is a validly formed address.

Example:

```
if (valid_email('email@somesite.com'))
{
    echo 'email is valid';
}
else
{
    echo 'email is not valid';
}
```

: All that this function does is to use PHP's native `filter_var()`: `!! (bool) filter_var($email, FILTER_VALIDATE_EMAIL)`;

send_email()

send_email (*\$recipient*, *\$subject*, *\$message*)

- **\$recipient** (*string*) – E-mail address
- **\$subject** (*string*) – Mail subject
- **\$message** (*string*) – Message body

bool

Sends an email using PHP's native [mail\(\)](#) function.

: All that this function does is to use PHP's native `mail: || mail($recipient, $subject, $message);`

For a more robust email solution, see CodeIgniter's *Email Library*.

10.14.8 File Helper

The File Helper file contains functions that assist in working with files.

Page Contents

- File Helper
 - Loading this Helper
 - [read_file\(\)](#)
 - [write_file\(\)](#)
 - [delete_files\(\)](#)
 - [get_filenames\(\)](#)
 - [get_dir_file_info\(\)](#)
 - [get_file_info\(\)](#)
 - [get_mime_by_extension\(\)](#)
 - [symbolic_permissions\(\)](#)
 - [octal_permissions\(\)](#)

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('file');
```

The following functions are available:

read_file()

read_file (*\$file*)

- **\$file** (*string*) – File path

string or FALSE on failure

Returns the data contained in the file specified in the path.

Example:

```
$string = read_file('./path/to/file.php');
```

The path can be a relative or full server path. Returns FALSE (boolean) on failure.

: The path is relative to your main site index.php file, NOT your controller or view files. CodeIgniter uses a front controller so paths are always relative to the main site index.

: This function is DEPRECATED. Use the native `file_get_contents()` instead.

: If your server is running an **open_basedir** restriction this function might not work if you are trying to access a file above the calling script.

write_file()

write_file(\$path, \$data, \$mode = 'wb')

- **\$path** (*string*) – File path
- **\$data** (*string*) – Data to write to file
- **\$mode** (*string*) – `fopen()` mode

bool

Writes data to the file specified in the path. If the file does not exist then the function will create it.

Example:

```
$data = 'Some file data';
if ( ! write_file('./path/to/file.php', $data) )
{
    echo 'Unable to write the file';
}
else
{
    echo 'File written!';
}
```

You can optionally set the write mode via the third parameter:

```
write_file('./path/to/file.php', $data, 'r+');
```

The default mode is 'wb'. Please see the [PHP user guide](#) for mode options.

: The path is relative to your main site index.php file, NOT your controller or view files. CodeIgniter uses a front controller so paths are always relative to the main site index.

: This function acquires an exclusive lock on the file while writing to it.

delete_files()

delete_files (*\$path*, *\$del_dir* = FALSE, *\$htdocs* = FALSE)

- **\$path** (*string*) – Directory path
- **\$del_dir** (*bool*) – Whether to also delete directories
- **\$htdocs** (*bool*) – Whether to skip deleting .htaccess and index page files

bool

Deletes ALL files contained in the supplied path.

Example:

```
delete_files('./path/to/directory/');
```

If the second parameter is set to TRUE, any directories contained within the supplied root path will be deleted as well.

Example:

```
delete_files('./path/to/directory/', TRUE);
```

: The files must be writable or owned by the system in order to be deleted.

get_filenames()

get_filenames (*\$source_dir*, *\$include_path* = FALSE)

- **\$source_dir** (*string*) – Directory path
- **\$include_path** (*bool*) – Whether to include the path as part of the filenames

array

Takes a server path as input and returns an array containing the names of all files contained within it. The file path can optionally be added to the file names by setting the second parameter to TRUE.

Example:

```
$controllers = get_filenames(APPPATH.'controllers/');
```

get_dir_file_info()

get_dir_file_info (*\$source_dir*, *\$top_level_only*)

- **\$source_dir** (*string*) – Directory path
- **\$top_level_only** (*bool*) – Whether to look only at the specified directory (excluding sub-directories)

array

Reads the specified directory and builds an array containing the filenames, filesize, dates, and permissions. Sub-folders contained within the specified path are only read if forced by sending the second parameter to FALSE, as this can be an intensive operation.

Example:

```
$models_info = get_dir_file_info(APPPATH.'models/');
```

get_file_info()

Given a file and path, returns (optionally) the *name*, *path*, *size* and *date modified* information attributes for a file. Second parameter allows you to explicitly declare what information you want returned.

Valid `$returned_values` options are: *name*, *size*, *date*, *readable*, *writable*, *executable* and *fileperms*.

: The *writable* attribute is checked via PHP's `is_writable()` function, which known to have issues on the IIS webserver. Consider using *fileperms* instead, which returns information from PHP's `fileperms()` function.

get_mime_by_extension()

get_mime_by_extension (*\$filename*)

- **\$filename** (*string*) – File name

string or FALSE on failure

Translates a filename extension into a MIME type based on *config/mimes.php*. Returns FALSE if it can't determine the type, or read the MIME config file.

```
$file = 'somefile.png';
echo $file.' is has a mime type of '.get_mime_by_extension($file);
```

: This is not an accurate way of determining file MIME types, and is here strictly for convenience. It should not be used for security purposes.

symbolic_permissions()

symbolic_permissions (*\$perms*)

- **\$perms** (*int*) – Permissions

string

Takes numeric permissions (such as is returned by `fileperms()`) and returns standard symbolic notation of file permissions.

```
echo symbolic_permissions(fileperms('./index.php')); // -rw-r--r--
```

octal_permissions()

octal_permissions (*\$perms*)

- **\$perms** (*int*) – Permissions

string

Takes numeric permissions (such as is returned by `fileperms()`) and returns a three character octal notation of file permissions.

```
echo octal_permissions(fileperms('./index.php')); // 644
```

10.14.9 Form Helper

The Form Helper file contains functions that assist in working with forms.

Page Contents

- Form Helper
 - Loading this Helper
 - `form_open()`
 - * Adding Attributes
 - * Adding Hidden Input Fields
 - `form_open_multipart()`
 - `form_hidden()`
 - `form_input()`
 - `form_password()`
 - `form_upload()`
 - `form_textarea()`
 - `form_dropdown()`
 - `form_multiselect()`
 - `form_fieldset()`
 - `form_fieldset_close()`
 - `form_checkbox()`
 - `form_radio()`
 - `form_label()`
 - `form_submit()`
 - `form_reset()`
 - `form_button()`
 - `form_close()`
 - `form_prep()`
 - `set_value()`
 - `set_select()`
 - `set_checkbox()`
 - `set_radio()`
 - `form_error()`
 - `validation_errors()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('form');
```

The following functions are available:

form_open()

```
form_open($action = '', $attributes = '', $hidden = array())
```

- **\$action** (*string*) – Form action/target URI string
- **\$attributes** (*array*) – HTML attributes
- **\$hidden** (*array*) – An array of hidden fields' definitions

string

Creates an opening form tag with a base URL **built from your config preferences**. It will optionally let you add form attributes and hidden input fields, and will always add the *accept-charset* attribute based on the charset value in your config file.

The main benefit of using this tag rather than hard coding your own HTML is that it permits your site to be more portable in the event your URLs ever change.

Here's a simple example:

```
echo form_open('email/send');
```

The above example would create a form that points to your base URL plus the “email/send” URI segments, like this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send">
```

Adding Attributes

Attributes can be added by passing an associative array to the second parameter, like this:

```
$attributes = array('class' => 'email', 'id' => 'myform');
echo form_open('email/send', $attributes);
```

Alternatively, you can specify the second parameter as a string:

```
echo form_open('email/send', 'class="email" id="myform"');
```

The above examples would create a form similar to this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send" class="email" id="myform">
```

Adding Hidden Input Fields

Hidden fields can be added by passing an associative array to the third parameter, like this:

```
$hidden = array('username' => 'Joe', 'member_id' => '234');
echo form_open('email/send', '', $hidden);
```

You can skip the second parameter by passing any falsy value to it.

The above example would create a form similar to this:

```
<form method="post" accept-charset="utf-8" action="http://example.com/index.php/email/send">
    <input type="hidden" name="username" value="Joe" />
    <input type="hidden" name="member_id" value="234" />
```

form_open_multipart()

form_open_multipart (*\$action* = '', *\$attributes* = array(), *\$hidden* = array())

- **\$action** (*string*) – Form action/target URI string
- **\$attributes** (*array*) – HTML attributes
- **\$hidden** (*array*) – An array of hidden fields' definitions

string

This function is absolutely identical to `form_open()` above, except that it adds a *multipart* attribute, which is necessary if you would like to use the form to upload files with.

form_hidden()

form_hidden (*\$name*, *\$value* = '')

- **\$name** (*string*) – Field name
- **\$value** (*string*) – Field value

string

Lets you generate hidden input fields. You can either submit a name/value string to create one field:

```
form_hidden('username', 'johndoe');
// Would produce: <input type="hidden" name="username" value="johndoe" />
```

... or you can submit an associative array to create multiple fields:

```
$data = array(
    'name'   => 'John Doe',
    'email'  => 'john@example.com',
    'url'    => 'http://example.com'
);

echo form_hidden($data);

/*
    Would produce:
    <input type="hidden" name="name" value="John Doe" />
    <input type="hidden" name="email" value="john@example.com" />
    <input type="hidden" name="url" value="http://example.com" />
*/
```

You can also pass an associative array to the value field:

```
$data = array(
    'name'   => 'John Doe',
    'email'  => 'john@example.com',
```

```

        'url'    => 'http://example.com'
    );

    echo form_hidden('my_array', $data);

    /*
        Would produce:

        <input type="hidden" name="my_array[name]" value="John Doe" />
        <input type="hidden" name="my_array[email]" value="john@example.com" />
        <input type="hidden" name="my_array[url]" value="http://example.com" />
    */

```

If you want to create hidden input fields with extra attributes:

```

$data = array(
    'type'    => 'hidden',
    'name'    => 'email',
    'id'      => 'hiddenemail',
    'value'   => 'john@example.com',
    'class'   => 'hiddenemail'
);

echo form_input($data);

/*
    Would produce:

    <input type="hidden" name="email" value="john@example.com" id="hiddenemail" class="hiddenemail" />
*/

```

form_input()

form_input (*\$data* = '', *\$value* = '', *\$extra* = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard text input field. You can minimally pass the field name and value in the first and second parameter:

```
echo form_input('username', 'johndoe');
```

Or you can pass an associative array containing any data you wish your form to contain:

```

$data = array(
    'name'      => 'username',
    'id'        => 'username',
    'value'     => 'johndoe',
    'maxlength' => '100',
    'size'      => '50',
    'style'     => 'width:50%'
);

```

```
echo form_input($data);
```

```
/*
```

```
    Would produce:
```

```
    <input type="text" name="username" value="johndoe" id="username" maxlength="100" size="50" st
*/
```

If you would like your form to contain some additional data, like JavaScript, you can pass it as a string in the third parameter:

```
$js = 'onClick="some_function()"';
echo form_input('username', 'johndoe', $js);
```

form_password()

form_password(\$data = '', \$value = '', \$extra = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it uses the “password” input type.

form_upload()

form_upload(\$data = '', \$value = '', \$extra = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it uses the “file” input type, allowing it to be used to upload files.

form_textarea()

form_textarea(\$data = '', \$value = '', \$extra = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_input()` function above except that it generates a “textarea” type.

form_dropdown()

form_dropdown (*\$name* = '', *\$options* = array(), *\$selected* = array(), *\$extra* = '')

- **\$name** (*string*) – Field name
- **\$options** (*array*) – An associative array of options to be listed
- **\$selected** (*array*) – List of fields to mark with the *selected* attribute
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you create a standard drop-down field. The first parameter will contain the name of the field, the second parameter will contain an associative array of options, and the third parameter will contain the value you wish to be selected. You can also pass an array of multiple items through the third parameter, and CodeIgniter will create a multiple select for you.

Example:

```
$options = array(
    'small'      => 'Small Shirt',
    'med'        => 'Medium Shirt',
    'large'      => 'Large Shirt',
    'xlarge'     => 'Extra Large Shirt',
);

$shirts_on_sale = array('small', 'large');
echo form_dropdown('shirts', $options, 'large');

/*
    Would produce:

    <select name="shirts">
        <option value="small">Small Shirt</option>
        <option value="med">Medium Shirt</option>
        <option value="large" selected="selected">Large Shirt</option>
        <option value="xlarge">Extra Large Shirt</option>
    </select>
*/

echo form_dropdown('shirts', $options, $shirts_on_sale);

/*
    Would produce:

    <select name="shirts" multiple="multiple">
        <option value="small" selected="selected">Small Shirt</option>
        <option value="med">Medium Shirt</option>
        <option value="large" selected="selected">Large Shirt</option>
        <option value="xlarge">Extra Large Shirt</option>
    </select>
*/
```

If you would like the opening `<select>` to contain additional data, like an id attribute or JavaScript, you can pass it as a string in the fourth parameter:

```
$js = 'id="shirts" onChange="some_function();"';
echo form_dropdown('shirts', $options, 'large', $js);
```

If the array passed as `$options` is a multidimensional array, then `form_dropdown()` will produce an `<optgroup>` with the array key as the label.

form_multiselect()

form_multiselect (*\$name* = '', *\$options* = array(), *\$selected* = array(), *\$extra* = '')

- **\$name** (*string*) – Field name
- **\$options** (*array*) – An associative array of options to be listed
- **\$selected** (*array*) – List of fields to mark with the *selected* attribute
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you create a standard multiselect field. The first parameter will contain the name of the field, the second parameter will contain an associative array of options, and the third parameter will contain the value or values you wish to be selected.

The parameter usage is identical to using `form_dropdown()` above, except of course that the name of the field will need to use POST array syntax, e.g. `foo[]`.

form_fieldset()

form_fieldset (*\$legend_text* = '', *\$attributes* = array())

- **\$legend_text** (*string*) – Text to put in the `<legend>` tag
- **\$attributes** (*array*) – Attributes to be set on the `<fieldset>` tag

string

Lets you generate fieldset/legend fields.

Example:

```
echo form_fieldset('Address Information');
echo "<p>fieldset content here</p>\n";
echo form_fieldset_close();

/*
    Produces:

        <fieldset>
            <legend>Address Information</legend>
            <p>form content here</p>
        </fieldset>
*/
```

Similar to other functions, you can submit an associative array in the second parameter if you prefer to set additional attributes:

```
$attributes = array(
    'id'      => 'address_info',
    'class'   => 'address_info'
);

echo form_fieldset('Address Information', $attributes);
echo "<p>fieldset content here</p>\n";
echo form_fieldset_close();

/*
    Produces:

    <fieldset id="address_info" class="address_info">
        <legend>Address Information</legend>
        <p>form content here</p>
    </fieldset>
*/
```

form_fieldset_close()

form_fieldset_close (*\$extra* = '')

- **\$extra** (*string*) – Anything to append after the closing tag, *as is*

string

Produces a closing `</fieldset>` tag. The only advantage to using this function is it permits you to pass data to it which will be added below the tag. For example

```
$string = '</div></div>';
echo form_fieldset_close($string);
// Would produce: </fieldset></div></div>
```

form_checkbox()

form_checkbox (*\$data* = '', *\$value* = '', *\$checked* = FALSE, *\$extra* = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$checked** (*bool*) – Whether to mark the checkbox as being *checked*
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a checkbox field. Simple example:

```
echo form_checkbox('newsletter', 'accept', TRUE);
// Would produce: <input type="checkbox" name="newsletter" value="accept" checked="checked" />
```

The third parameter contains a boolean TRUE/FALSE to determine whether the box should be checked or not.

Similar to the other form functions in this helper, you can also pass an array of attributes to the function:

```
$data = array(
    'name'          => 'newsletter',
    'id'            => 'newsletter',
    'value'         => 'accept',
    'checked'       => TRUE,
    'style'         => 'margin:10px'
);

echo form_checkbox($data);
// Would produce: <input type="checkbox" name="newsletter" id="newsletter" value="accept" checked="checked" />
```

Also as with other functions, if you would like the tag to contain additional data like JavaScript, you can pass it as a string in the fourth parameter:

```
$js = 'onClick="some_function()"';
echo form_checkbox('newsletter', 'accept', TRUE, $js)
```

form_radio()

form_radio (*\$data* = '', *\$value* = '', *\$checked* = FALSE, *\$extra* = '')

- **\$data** (*array*) – Field attributes data
- **\$value** (*string*) – Field value
- **\$checked** (*bool*) – Whether to mark the radio button as being *checked*
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

This function is identical in all respects to the `form_checkbox()` function above except that it uses the “radio” input type.

form_label()

form_label (*\$label_text* = '', *\$id* = '', *\$attributes* = array())

- **\$label_text** (*string*) – Text to put in the <label> tag
- **\$id** (*string*) – ID of the form element that we’re making a label for
- **\$attributes** (*string*) – HTML attributes

string

Lets you generate a <label>. Simple example:

```
echo form_label('What is your Name', 'username');
// Would produce: <label for="username">What is your Name</label>
```

Similar to other functions, you can submit an associative array in the third parameter if you prefer to set additional attributes.

Example:

```
$attributes = array(
    'class' => 'mycustomclass',
    'style' => 'color: #000;'
);

echo form_label('What is your Name', 'username', $attributes);
// Would produce: <label for="username" class="mycustomclass" style="color: #000;">What is your Name
```

form_submit()

form_submit (\$data = '', \$value = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$value** (*string*) – Button value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard submit button. Simple example:

```
echo form_submit('mysubmit', 'Submit Post!');
// Would produce: <input type="submit" name="mysubmit" value="Submit Post!" />
```

Similar to other functions, you can submit an associative array in the first parameter if you prefer to set your own attributes. The third parameter lets you add extra data to your form, like JavaScript.

form_reset()

form_reset (\$data = '', \$value = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$value** (*string*) – Button value
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard reset button. Use is identical to `form_submit()`.

form_button()

form_button (\$data = '', \$content = '', \$extra = '')

- **\$data** (*string*) – Button name
- **\$content** (*string*) – Button label
- **\$extra** (*string*) – Extra attributes to be added to the tag *as is*

string

Lets you generate a standard button element. You can minimally pass the button name and content in the first and second parameter:

```
echo form_button('name', 'content');  
// Would produce: <button name="name" type="button">Content</button>
```

Or you can pass an associative array containing any data you wish your form to contain:

```
$data = array(  
    'name'          => 'button',  
    'id'            => 'button',  
    'value'         => 'true',  
    'type'          => 'reset',  
    'content'       => 'Reset'  
);  
  
echo form_button($data);  
// Would produce: <button name="button" id="button" value="true" type="reset">Reset</button>
```

If you would like your form to contain some additional data, like JavaScript, you can pass it as a string in the third parameter:

```
$js = 'onClick="some_function()"';  
echo form_button('mybutton', 'Click Me', $js);
```

form_close()

form_close(\$extra = '')

- **\$extra** (*string*) – Anything to append after the closing tag, *as is*

string

Produces a closing `</form>` tag. The only advantage to using this function is it permits you to pass data to it which will be added below the tag. For example:

```
$string = '</div></div>';  
echo form_close($string);  
// Would produce: </form> </div></div>
```

form_prep()

form_prep(\$str = '', \$is_textarea = FALSE)

- **\$str** (*string*) – Value to escape
- **\$is_textarea** (*bool*) – Whether we're preparing for `<textarea>` or a regular input tag

string

Allows you to safely use HTML and characters such as quotes within form elements without breaking out of the form.

Consider this example:

```
$string = 'Here is a string containing "quoted" text.';  
<input type="text" name="myform" value="$string" />
```

Since the above string contains a set of quotes it will cause the form to break. The `form_prep()` function converts HTML so that it can be used safely:

```
<input type="text" name="myform" value="<?php echo form_prep($string); ?>" />
```

: If you use any of the form helper functions listed in this page the form values will be prepped automatically, so there is no need to call this function. Use it only if you are creating your own form elements.

set_value()

set_value (*\$field* = '', *\$default* = '', *\$is_textarea* = FALSE)

- **\$field** (*string*) – Field name
- **\$default** (*string*) – Default value
- **\$is_textarea** (*bool*) – Whether we're setting <textarea> content

string

Permits you to set the value of an input form or textarea. You must supply the field name via the first parameter of the function. The second (optional) parameter allows you to set a default value for the form.

Example:

```
<input type="text" name="quantity" value="<?=set_value('quantity', '0');?>" size="50" />
```

The above form will show “0” when loaded for the first time.

set_select()

set_select (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

If you use a <select> menu, this function permits you to display the menu item that was selected.

The first parameter must contain the name of the select menu, the second parameter must contain the value of each item, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<select name="myselect">
    <option value="one" <?php echo set_select('myselect', 'one', TRUE); ?> >One</option>
    <option value="two" <?php echo set_select('myselect', 'two'); ?> >Two</option>
    <option value="three" <?php echo set_select('myselect', 'three'); ?> >Three</option>
</select>
```

set_checkbox()

set_checkbox (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

Permits you to display a checkbox in the state it was submitted.

The first parameter must contain the name of the checkbox, the second parameter must contain its value, and the third (optional) parameter lets you set an item as the default (use boolean TRUE/FALSE).

Example:

```
<input type="checkbox" name="mycheck" value="1" <?php echo set_checkbox('mycheck', '1'); ?> />
<input type="checkbox" name="mycheck" value="2" <?php echo set_checkbox('mycheck', '2'); ?> />
```

set_radio()

set_radio (*\$field* = '', *\$value* = '', *\$default* = FALSE)

- **\$field** (*string*) – Field name
- **\$value** (*string*) – Value to check for
- **\$default** (*string*) – Whether the value is also a default one

string

Permits you to display radio buttons in the state they were submitted. This function is identical to the `set_checkbox()` function above.

Example:

```
<input type="radio" name="myradio" value="1" <?php echo set_radio('myradio', '1', TRUE); ?> />
<input type="radio" name="myradio" value="2" <?php echo set_radio('myradio', '2'); ?> />
```

: If you are using the Form Validation class, you must always specify a rule for your field, even if empty, in order for the `set_*()` functions to work. This is because if a Form Validation object is defined, the control for `set_*()` is handed over to a method of the class instead of the generic helper function.

form_error()

form_error (*\$field* = '', *\$prefix* = '', *\$suffix* = '')

- **\$field** (*string*) – Field name
- **\$prefix** (*string*) – Error opening tag
- **\$suffix** (*string*) – Error closing tag

string

Returns a validation error message from the *Form Validation Library*, associated with the specified field name. You can optionally specify opening and closing tag(s) to put around the error message.

Example:

```
// Assuming that the 'username' field value was incorrect:
echo form_error('myfield', '<div class="error">', '</div>');

// Would produce: <div class="error">Error message associated with the "username" field.</div>
```

validation_errors()

validation_errors (\$prefix = '', \$suffix = '')

- **\$prefix** (*string*) – Error opening tag
- **\$suffix** (*string*) – Error closing tag

string

Similarly to the `form_error()` function, returns all validation error messages produced by the *Form Validation Library*, with optional opening and closing tags around each of the messages.

Example:

```
echo validation_errors('<span class="error">', '</span>');

/*
    Would produce, e.g.:

    <span class="error">The "email" field doesn't contain a valid e-mail address!</span>
    <span class="error">The "password" field doesn't match the "repeat_password" field!</span>

*/
```

10.14.10 HTML Helper

The HTML Helper file contains functions that assist in working with HTML.

Page Contents

- HTML Helper
 - Loading this Helper
 - `br()`
 - `heading()`
 - `img()`
 - `link_tag()`
 - `nbs()`
 - `ul()` and `ol()`
 - `meta()`
 - `doctype()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('html');
```

The following functions are available:

br()

br (*\$count* = 1)

- **\$count** (*int*) – Number of times to repeat the tag
- string

Generates line break tags (
) based on the number you submit. Example:

```
echo br(3);
```

The above would produce:

heading()

heading (*\$data* = '', *\$h* = '1', *\$attributes* = '')

- **\$data** (*string*) – Content
 - **\$h** (*string*) – Heading level
 - **\$attributes** (*array*) – HTML attributes
- string

Lets you create HTML heading tags. The first parameter will contain the data, the second the size of the heading. Example:

```
echo heading('Welcome!', 3);
```

The above would produce: <h3>Welcome!</h3>

Additionally, in order to add attributes to the heading tag such as HTML classes, ids or inline styles, a third parameter is available:

```
echo heading('Welcome!', 3, 'class="pink"');
```

The above code produces: <h3 class="pink">Welcome!</h3>

img()

img (*\$src* = '', *\$index_page* = FALSE, *\$attributes* = '')

- **\$src** (*string*) – Image source data
- **\$index_page** (*bool*) – Whether to treat \$src as a routed URI string

- **\$attributes** (*array*) – HTML attributes

string

Lets you create HTML `` tags. The first parameter contains the image source. Example:

```
echo img('images/picture.jpg'); // gives 
```

There is an optional second parameter that is a TRUE/FALSE value that specifies if the *src* should have the page specified by `$config['index_page']` added to the address it creates. Presumably, this would be if you were using a media controller:

```
echo img('images/picture.jpg', TRUE); // gives 
```

Additionally, an associative array can be passed to the `img()` function for complete control over all attributes and values. If an *alt* attribute is not provided, CodeIgniter will generate an empty string.

Example:

```
$image_properties = array(
    'src'    => 'images/picture.jpg',
    'alt'    => 'Me, demonstrating how to eat 4 slices of pizza at one time',
    'class' => 'post_images',
    'width' => '200',
    'height'=> '200',
    'title' => 'That was quite a night',
    'rel'    => 'lightbox'
);

img($image_properties);
// 
```

link_tag()

link_tag (*\$href* = '', *\$rel* = 'stylesheet', *\$type* = 'text/css', *\$title* = '', *\$media* = '', *\$index_page* = FALSE)

- **\$href** (*string*) – What are we linking to
- **\$rel** (*string*) – Relation type
- **\$type** (*string*) – Type of the related document
- **\$title** (*string*) – Link title
- **\$media** (*string*) – Media type
- **\$index_page** (*bool*) – Whether to treat *\$src* as a routed URI string

string

Lets you create HTML `<link />` tags. This is useful for stylesheet links, as well as other links. The parameters are *href*, with optional *rel*, *type*, *title*, *media* and *index_page*.

index_page is a boolean value that specifies if the *href* should have the page specified by `$config['index_page']` added to the address it creates.

Example:

```
echo link_tag('css/mystyles.css');
// gives <link href="http://site.com/css/mystyles.css" rel="stylesheet" type="text/css" />
```

```

$attributes = array(
    'class' => 'boldlist',
    'id'    => 'mylist'
);

echo ul($list, $attributes);

```

The above code will produce this:

```

<ul class="boldlist" id="mylist">
    <li>red</li>
    <li>blue</li>
    <li>green</li>
    <li>yellow</li>
</ul>

```

Here is a more complex example, using a multi-dimensional array:

```

$attributes = array(
    'class' => 'boldlist',
    'id'    => 'mylist'
);

$list = array(
    'colors' => array(
        'red',
        'blue',
        'green'
    ),
    'shapes' => array(
        'round',
        'square',
        'circles' => array(
            'ellipse',
            'oval',
            'sphere'
        )
    ),
    'moods' => array(
        'happy',
        'upset' => array(
            'defeated' => array(
                'dejected',
                'disheartened',
                'depressed'
            ),
            'annoyed',
            'cross',
            'angry'
        )
    )
);

echo ul($list, $attributes);

```

The above code will produce this:

```

<ul class="boldlist" id="mylist">
    <li>colors

```

```
        <ul>
            <li>red</li>
            <li>blue</li>
            <li>green</li>
        </ul>
    </li>
    <li>shapes
        <ul>
            <li>round</li>
            <li>suare</li>
            <li>circles
                <ul>
                    <li>ellipse</li>
                    <li>oval</li>
                    <li>sphere</li>
                </ul>
            </li>
        </ul>
    </li>
    <li>moods
        <ul>
            <li>happy</li>
            <li>upset
                <ul>
                    <li>defeated
                        <ul>
                            <li>dejected</li>
                            <li>disheartened</li>
                            <li>depressed</li>
                        </ul>
                    </li>
                    <li>annoyed</li>
                    <li>cross</li>
                    <li>angry</li>
                </ul>
            </li>
        </ul>
    </li>
</ul>
```

ol (*\$list*, *\$attributes* = '')

- **\$list** (*array*) – List entries
- **\$attributes** (*array*) – HTML attributes

string

Identical to `ul()`, only it produces the `` tag for ordered lists instead of ``.

meta()

meta (*\$name* = '', *\$content* = '', *\$type* = 'name', *\$newline* = "n")

- **\$name** (*string*) – Meta name

- **\$content** (*string*) – Meta content
- **\$type** (*string*) – Meta type
- **\$newline** (*string*) – Newline character

string

Helps you generate meta tags. You can pass strings to the function, or simple arrays, or multidimensional ones.

Examples:

```
echo meta('description', 'My Great site');
// Generates: <meta name="description" content="My Great Site" />

echo meta('Content-type', 'text/html; charset=utf-8', 'equiv');
// Note the third parameter. Can be "equiv" or "name"
// Generates: <meta http-equiv="Content-type" content="text/html; charset=utf-8" />

echo meta(array('name' => 'robots', 'content' => 'no-cache'));
// Generates: <meta name="robots" content="no-cache" />

$meta = array(
    array(
        'name' => 'robots',
        'content' => 'no-cache'
    ),
    array(
        'name' => 'description',
        'content' => 'My Great Site'
    ),
    array(
        'name' => 'keywords',
        'content' => 'love, passion, intrigue, deception'
    ),
    array(
        'name' => 'robots',
        'content' => 'no-cache'
    ),
    array(
        'name' => 'Content-type',
        'content' => 'text/html; charset=utf-8', 'type' => 'equiv'
    )
);

echo meta($meta);
// Generates:
// <meta name="robots" content="no-cache" />
// <meta name="description" content="My Great Site" />
// <meta name="keywords" content="love, passion, intrigue, deception" />
// <meta name="robots" content="no-cache" />
// <meta http-equiv="Content-type" content="text/html; charset=utf-8" />
```

doctype()

doctype (*\$type* = 'xhtml1-strict')

- **\$type** (*string*) – Doctype name

Helps you generate document type declarations, or DTD's. XHTML 1.0 Strict is used by default, but many doctypes are available.

Example:

```
echo doctype(); // <!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">

echo doctype('html4-trans'); // <!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/DTD/html4-trans.dtd">
```

The following is a list of doctype choices. These are configurable, and pulled from application/config/doctypes.php

Doctype	Option	Result
XHTML 1.1	doctype('xhtml11')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.1//EN" "http://www.w3.org/TR/xhtml11/DTD/xhtml11.dtd">
XHTML 1.0 Strict	doctype('xhtml1-strict')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Strict//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-strict.dtd">
XHTML 1.0 Transitional	doctype('xhtml1-trans')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Transitional//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-transitional.dtd">
XHTML 1.0 Frameset	doctype('xhtml1-frame')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML 1.0 Frameset//EN" "http://www.w3.org/TR/xhtml1/DTD/xhtml1-frameset.dtd">
XHTML Basic 1.1	doctype('xhtml-basic11')	<!DOCTYPE html PUBLIC "-//W3C//DTD XHTML Basic 1.1//EN" "http://www.w3.org/TR/xhtml-basic/xhtml-basic11.dtd">
HTML 5	doctype('html5')	<!DOCTYPE html>
HTML 4 Strict	doctype('html4-strict')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01//EN" "http://www.w3.org/TR/html4/strict.dtd">
HTML 4 Transitional	doctype('html4-trans')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Transitional//EN" "http://www.w3.org/TR/html4/loose.dtd">
HTML 4 Frameset	doctype('html4-frame')	<!DOCTYPE HTML PUBLIC "-//W3C//DTD HTML 4.01 Frameset//EN" "http://www.w3.org/TR/html4/frameset.dtd">
MathML 1.01	doctype('mathml1')	<!DOCTYPE math SYSTEM "http://www.w3.org/Math/DTD/mathml1/mathml.dtd">
MathML 2.0	doctype('mathml2')	<!DOCTYPE math PUBLIC "-//W3C//DTD MathML 2.0//EN" "http://www.w3.org/Math/DTD/mathml2/mathml2.dtd">
SVG 1.0	doctype('svg10')	<!DOCTYPE svg PUBLIC "-//W3C//DTD SVG 1.0//EN" "http://www.w3.org/TR/2001/REC-SVG-20010904/DTD/svg10.dtd">

10.14.11 Inflector Helper

The Inflector Helper file contains functions that permits you to change words to plural, singular, camel case, etc.

Page Contents

- Inflector Helper
 - Loading this Helper
 - singular()
 - plural()
 - camelize()
 - underscore()
 - humanize()
 - is_countable()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('inflector');
```

The following functions are available:

singular()

singular (*\$str*)

- **\$str** (*string*) – Input string
string

Changes a plural word to singular. Example:

```
echo singular('dogs'); // Prints 'dog'
```

plural()

plural (*\$str*)

- **\$str** (*string*) – Input string
string

Changes a singular word to plural. Example:

```
echo plural('dog'); // Prints 'dogs'
```

camelize()

camelize (*\$str*)

- **\$str** (*string*) – Input string

string

Changes a string of words separated by spaces or underscores to camel case. Example:

```
echo camelize('my_dog_spot'); // Prints 'myDogSpot'
```

underscore()

camelize (*\$str*)

- **\$str** (*string*) – Input string

string

Takes multiple words separated by spaces and underscores them. Example:

```
echo underscore('my dog spot'); // Prints 'my_dog_spot'
```

humanize()

camelize (*\$str*)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Input separator

string

Takes multiple words separated by underscores and adds spaces between them. Each word is capitalized.

Example:

```
echo humanize('my_dog_spot'); // Prints 'My Dog Spot'
```

To use dashes instead of underscores:

```
echo humanize('my-dog-spot', '-'); // Prints 'My Dog Spot'
```

is_countable()

is_countable (*\$word*)

- **\$word** (*string*) – Input string

bool

Checks if the given word has a plural version. Example:

```
is_countable('equipment'); // Returns FALSE
```

10.14.12 Language Helper

The Language Helper file contains functions that assist in working with language files.

Page Contents

- Language Helper
 - Loading this Helper
 - lang()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('language');
```

The following functions are available:

lang()

```
lang($line, $for = '', $attributes = array())
```

- **\$line** (*string*) – Language line key
- **\$for** (*string*) – HTML “for” attribute (ID of the element we’re creating a label for)
- **\$attributes** (*array*) – Any additional HTML attributes

string

This function returns a line of text from a loaded language file with simplified syntax that may be more desirable for view files than `CI_Lang::line()`.

Example:

```
echo lang('language_key', 'form_item_id', array('class' => 'myClass'));
// Outputs: <label for="form_item_id" class="myClass">Language line</label>
```

10.14.13 Number Helper

The Number Helper file contains functions that help you work with numeric data.

Page Contents

- Number Helper
 - Loading this Helper
 - byte_format()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('number');
```

The following functions are available:

byte_format()

byte_format (*\$num*, *\$precision = 1*)

- **\$num** (*mixed*) – Number of bytes
 - **\$precision** (*int*) – Floating point precision
- string

Formats numbers as bytes, based on size, and adds the appropriate suffix. Examples:

```
echo byte_format(456); // Returns 456 Bytes
echo byte_format(4567); // Returns 4.5 KB
echo byte_format(45678); // Returns 44.6 KB
echo byte_format(456789); // Returns 447.8 KB
echo byte_format(3456789); // Returns 3.3 MB
echo byte_format(12345678912345); // Returns 1.8 GB
echo byte_format(123456789123456789); // Returns 11,228.3 TB
```

An optional second parameter allows you to set the precision of the result:

```
echo byte_format(45678, 2); // Returns 44.61 KB
```

: The text generated by this function is found in the following language file: *language/<your_lang>/number_lang.php*

10.14.14 Path Helper

The Path Helper file contains functions that permits you to work with file paths on the server.

Page Contents

- Path Helper
 - Loading this Helper
 - set_realpath()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('path');
```

The following functions are available:

set_realpath()

set_realpath(\$path, \$check_existence = FALSE)

- **\$path** (*string*) – Path
- **\$check_existence** (*bool*) – Whether to check if the path actually exists

string

This function will return a server path without symbolic links or relative directory structures. An optional second argument will cause an error to be triggered if the path cannot be resolved.

Examples:

```
$file = '/etc/php5/apache2/php.ini';
echo set_realpath($file); // Prints '/etc/php5/apache2/php.ini'
```

```
$non_existent_file = '/path/to/non-exist-file.txt';
echo set_realpath($non_existent_file, TRUE); // Shows an error, as the path cannot be resolved
echo set_realpath($non_existent_file, FALSE); // Prints '/path/to/non-exist-file.txt'
```

```
$directory = '/etc/php5';
echo set_realpath($directory); // Prints '/etc/php5/'
```

```
$non_existent_directory = '/path/to/nowhere';
echo set_realpath($non_existent_directory, TRUE); // Shows an error, as the path cannot be resolved
echo set_realpath($non_existent_directory, FALSE); // Prints '/path/to/nowhere'
```

10.14.15 Security Helper

The Security Helper file contains security related functions.

Page Contents

- Security Helper
 - Loading this Helper
 - xss_clean()
 - sanitize_filename()
 - do_hash()
 - strip_image_tags()
 - encode_php_tags()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('security');
```

The following functions are available:

xss_clean()

xss_clean (*\$str*, *\$is_image* = *FALSE*)

- **\$str** (*string*) – Input data
- **\$is_image** (*bool*) – Whether we’re dealing with an image

string

Provides Cross Site Script Hack filtering.

This function is an alias for `CI_Input::xss_clean()`. For more info, please see the *Input Library* documentation.

sanitize_filename()

sanitize_filename (*\$filename*)

- **\$filename** (*string*) – Filename

string

Provides protection against directory traversal.

This function is an alias for `CI_Security::sanitize_filename()`. For more info, please see the *Security Library* documentation.

do_hash()

do_hash (*\$str*, *\$type* = *'sha1'*)

- **\$str** (*string*) – Input
- **\$type** (*string*) – Algorithm

string

Permits you to create one way hashes suitable for encrypting passwords. Will use SHA1 by default.

See [hash_algos\(\)](#) for a full list of supported algorithms.

Examples:

```
$str = do_hash($str); // SHA1
$str = do_hash($str, 'md5'); // MD5
```

: This function was formerly named `dohash()`, which has been removed in favor of `do_hash()`.

: This function is DEPRECATED. Use the native `hash()` instead.

strip_image_tags()

strip_image_tags (\$str)

- **\$str** (*string*) – Input

string

This is a security function that will strip image tags from a string. It leaves the image URL as plain text.

Example:

```
$string = strip_image_tags($string);
```

This function is an alias for `CI_Security::strip_image_tags()`. For more info, please see the *Security Library* documentation.

encode_php_tags()

encode_php_tags (\$str)

- **\$str** (*string*) – Input

string

This is a security function that converts PHP tags to entities.

Example:

```
$string = encode_php_tags($string);
```

10.14.16 Smiley Helper

The Smiley Helper file contains functions that let you manage smileys (emoticons).

Page Contents

- Smiley Helper
 - Loading this Helper
 - Overview
 - Clickable Smileys Tutorial
 - * The Controller
 - * Field Aliases
 - get_clickable_smileys()
 - smiley_js()
 - parse_smileys()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('smiley');
```

Overview

The Smiley helper has a renderer that takes plain text smileys, like :-), and turns them into a image representation, like . It also lets you display a set of smiley images that when clicked will be inserted into a form field. For example, if you have a blog that allows user commenting you can show the smileys next to the comment form. Your users can click a desired smiley and with the help of some JavaScript it will be placed into the form field.

Clickable Smileys Tutorial

Here is an example demonstrating how you might create a set of clickable smileys next to a form field. This example requires that you first download and install the smiley images, then create a controller and the View as described.

: Before you begin, please [download the smiley images](#) and put them in a publicly accessible place on your server. This helper also assumes you have the smiley replacement array located at *application/config/smileys.php*

The Controller

In your **application/controllers/** directory, create a file called **Smileys.php** and place the code below in it.

: Change the URL in the `get_clickable_smileys()` function below so that it points to your smiley folder.

You'll notice that in addition to the smiley helper, we are also using the *Table Class*:

```
<?php
```

```
class Smileys extends CI_Controller {

    public function index()
    {
        $this->load->helper('smiley');
        $this->load->library('table');

        $image_array = get_clickable_smileys('http://example.com/images/smileys/', 'comments');
        $col_array = $this->table->make_columns($image_array, 8);

        $data['smiley_table'] = $this->table->generate($col_array);
        $this->load->view('smiley_view', $data);
    }

}
```

In your **application/views/** folder, create a file called **smiley_view.php** and place this code in it:

```
<html>
    <head>
        <title>Smileys</title>
        <?php echo smiley_js(); ?>
    </head>
    <body>
        <form name="blog">
```

```

        <textarea name="comments" id="comments" cols="40" rows="4"></textarea>
    </form>
    <p>Click to insert a smiley!</p>
    <?php echo $smiley_table; ?> </body> </html>
    When you have created the above controller and view, load it by visiting http://www.
</body>
</html>

```

Field Aliases

When making changes to a view it can be inconvenient to have the field id in the controller. To work around this, you can give your smiley links a generic name that will be tied to a specific id in your view.

```
$image_array = get_smiley_links("http://example.com/images/smileys/", "comment_textarea_alias");
```

To map the alias to the field id, pass them both into the `smiley_js()` function:

```
$image_array = smiley_js("comment_textarea_alias", "comments");
```

get_clickable_smileys()

get_clickable_smileys (*\$image_url*, *\$alias* = '', *\$smileys* = NULL)

- **\$image_url** (*string*) – URL path to the smileys directory
- **\$alias** (*string*) – Field alias

array

Returns an array containing your smiley images wrapped in a clickable link. You must supply the URL to your smiley folder and a field id or field alias.

Example:

```
$image_array = get_smiley_links("http://example.com/images/smileys/", "comment");
```

smiley_js()

smiley_js (*\$alias* = '', *\$field_id* = '', *\$inline* = TRUE)

- **\$alias** (*string*) – Field alias
- **\$field_id** (*string*) – Field ID
- **\$inline** (*bool*) – Whether we're inserting an inline smiley

Generates the JavaScript that allows the images to be clicked and inserted into a form field. If you supplied an alias instead of an id when generating your smiley links, you need to pass the alias and corresponding form id into the function. This function is designed to be placed into the `<head>` area of your web page.

Example:

```
<?php echo smiley_js(); ?>
```

parse_smileys()

parse_smileys (*\$str* = '', *\$image_url* = '', *\$smileys* = *NULL*)

- **\$str** (*string*) – Text containing smiley codes
- **\$image_url** (*string*) – URL path to the smileys directory
- **\$smileys** (*array*) – An array of smileys

string

Takes a string of text as input and replaces any contained plain text smileys into the image equivalent. The first parameter must contain your string, the second must contain the URL to your smiley folder

Example:

```
$str = 'Here are some smileys: :-) ;-)';  
$str = parse_smileys($str, "http://example.com/images/smileys/");  
echo $str;
```

10.14.17 String Helper

The String Helper file contains functions that assist in working with strings.

Page Contents

- String Helper
 - Loading this Helper
 - random_string()
 - increment_string()
 - alternator()
 - repeater()
 - reduce_double_slashes()
 - strip_slashes()
 - trim_slashes()
 - reduce_multiples()
 - quotes_to_entities()
 - strip_quotes()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('string');
```

The following functions are available:

random_string()

random_string (*\$type* = 'alnum', *\$len* = 8)

- **\$type** (*string*) – Randomization type
- **\$len** (*int*) – Output string length

string

Generates a random string based on the type and length you specify. Useful for creating passwords or generating random hashes.

The first parameter specifies the type of string, the second parameter specifies the length. The following choices are available:

- **alpha**: A string with lower and uppercase letters only.
- **alnum**: Alpha-numeric string with lower and uppercase characters.
- **basic**: A random number based on `mt_rand()`.
- **numeric**: Numeric string.
- **nozero**: Numeric string with no zeros.
- **md5**: An encrypted random number based on `md5()` (fixed length of 32).
- **sha1**: An encrypted random number based on `sha1()` (fixed length of 40).

Usage example:

```
echo random_string('alnum', 16);
```

: Usage of the *unique* and *encrypt* types is DEPRECATED. They are just aliases for *md5* and *sha1* respectively.

increment_string()

increment_string (*\$str*, *\$separator* = '_', *\$first* = 1)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Separator to append a duplicate number with
- **\$first** (*int*) – Starting number

string

Increments a string by appending a number to it or increasing the number. Useful for creating “copies” or a file or duplicating database content which has unique titles or slugs.

Usage example:

```
echo increment_string('file', '_'); // "file_1"
echo increment_string('file', '- ', 2); // "file-2"
echo increment_string('file_4'); // "file_5"
```

alternator()

alternator (*\$args*)

- **\$args** (*mixed*) – A variable number of arguments

mixed

Allows two or more items to be alternated between, when cycling through a loop. Example:

```
for ($i = 0; $i < 10; $i++)
{
    echo alternator('string one', 'string two');
}
```

You can add as many parameters as you want, and with each iteration of your loop the next item will be returned.

```
for ($i = 0; $i < 10; $i++)
{
    echo alternator('one', 'two', 'three', 'four', 'five');
}
```

: To use multiple separate calls to this function simply call the function with no arguments to re-initialize.

repeater()

repeater (*\$data*, *\$num* = 1)

- **\$data** (*string*) – Input
- **\$num** (*int*) – Number of times to repeat

string

Generates repeating copies of the data you submit. Example:

```
$string = "\n";
echo repeater($string, 30);
```

The above would generate 30 newlines.

: This function is DEPRECATED. Use the native `str_repeat()` instead.

reduce_double_slashes()

reduce_double_slashes (*\$str*)

- **\$str** (*string*) – Input string

string

Converts double slashes in a string to a single slash, except those found in URL protocol prefixes (e.g. <http://>).

Example:

```
$string = "http://example.com//index.php";
echo reduce_double_slashes($string); // results in "http://example.com/index.php"
```

strip_slashes()

strip_slashes (*\$data*)

- **\$data** (*array*) – Input

array

Removes any slashes from an array of strings.

Example:

```
$str = array(
    'question' => 'Is your name O\'reilly?',
    'answer' => 'No, my name is O\'connor.'
);

$str = strip_slashes($str);
```

The above will return the following array:

```
array(
    'question' => "Is your name O'reilly?",
    'answer' => "No, my name is O'connor."
);
```

: For historical reasons, this function will also accept and handle string inputs. This however makes it just an alias for `stripslashes()`.

trim_slashes()

trim_slashes (*\$str*)

- **\$str** (*string*) – Input string

string

Removes any leading/trailing slashes from a string. Example:

```
$string = "/this/that/theother/";
echo trim_slashes($string); // results in this/that/theother
```

: This function is DEPRECATED. Use the native `trim()` instead: `|| trim($str, '/')`;

reduce_multiples()

reduce_multiples (*\$str*, *\$character* = `'`, *\$trim* = *FALSE*)

- **\$str** (*string*) – Text to search in
- **\$character** (*string*) – Character to reduce
- **\$trim** (*bool*) – Whether to also trim the specified character

string

Reduces multiple instances of a particular character occurring directly after each other. Example:

```
$string = "Fred, Bill,, Joe, Jimmy";  
$string = reduce_multiples($string, ","); //results in "Fred, Bill, Joe, Jimmy"
```

If the third parameter is set to TRUE it will remove occurrences of the character at the beginning and the end of the string. Example:

```
$string = ",Fred, Bill,, Joe, Jimmy,";  
$string = reduce_multiples($string, " ", TRUE); //results in "Fred, Bill, Joe, Jimmy"
```

quotes_to_entities()

quotes_to_entities (\$str)

- **\$str** (*string*) – Input string

string

Converts single and double quotes in a string to the corresponding HTML entities. Example:

```
$string = "Joe's \"dinner\"";  
$string = quotes_to_entities($string); //results in "Joe&#39;s &quot;dinner&quot;"
```

strip_quotes()

strip_quotes (\$str)

- **\$str** (*string*) – Input string

string

Removes single and double quotes from a string. Example:

```
$string = "Joe's \"dinner\"";  
$string = strip_quotes($string); //results in "Joes dinner"
```

10.14.18 Text Helper

The Text Helper file contains functions that assist in working with text.

Page Contents

- Text Helper
 - Loading this Helper
 - word_limiter()
 - character_limiter()
 - ascii_to_entities()
 - entities_to_ascii()
 - convert_accented_characters()
 - word_censor()
 - highlight_code()
 - highlight_phrase()
 - word_wrap()
 - ellipsis()

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('text');
```

The following functions are available:

word_limiter()

```
word_limiter($str, $limit = 100, $end_char = '&#8230;')
```

- **\$str** (*string*) – Input string
- **\$limit** (*int*) – Limit
- **\$end_char** (*string*) – End character (usually an ellipsis)

string

Truncates a string to the number of *words* specified. Example:

```
$string = "Here is a nice text string consisting of eleven words.";
$string = word_limiter($string, 4);
// Returns: Here is a nice...
```

The third parameter is an optional suffix added to the string. By default it adds an ellipsis.

character_limiter()

```
character_limiter($str, $n = 500, $end_char = '&#8230;')
```

- **\$str** (*string*) – Input string
- **\$n** (*int*) – Number of characters
- **\$end_char** (*string*) – End character (usually an ellipsis)

string

Truncates a string to the number of *characters* specified. It maintains the integrity of words so the character count may be slightly more or less than what you specify.

Example:

```
$string = "Here is a nice text string consisting of eleven words.";
$string = character_limiter($string, 20);
// Returns: Here is a nice text string...
```

The third parameter is an optional suffix added to the string, if undeclared this helper uses an ellipsis.

: If you need to truncate to an exact number of characters please see the *ellipsesize()* function below.

ascii_to_entities()

ascii_to_entities (*\$str*)

- **\$str** (*string*) – Input string

string

Converts ASCII values to character entities, including high ASCII and MS Word characters that can cause problems when used in a web page, so that they can be shown consistently regardless of browser settings or stored reliably in a database. There is some dependence on your server's supported character sets, so it may not be 100% reliable in all cases, but for the most part it should correctly identify characters outside the normal range (like accented characters).

Example:

```
$string = ascii_to_entities($string);
```

entities_to_ascii()

This function does the opposite of `ascii_to_entities()`. It turns character entities back into ASCII.

convert_accented_characters()

convert_accented_characters (*\$str*)

- **\$str** (*string*) – Input string

string

Transliterates high ASCII characters to low ASCII equivalents. Useful when non-English characters need to be used where only standard ASCII characters are safely used, for instance, in URLs.

Example:

```
$string = convert_accented_characters($string);
```

: This function uses a companion config file *application/config/foreign_chars.php* to define the to and from array for transliteration.

word_censor()

word_censor (*\$str*, *\$censored*, *\$replacement* = '')

- **\$str** (*string*) – Input string
- **\$censored** (*array*) – List of bad words to censor
- **\$replacement** (*string*) – What to replace bad words with

string

Enables you to censor words within a text string. The first parameter will contain the original string. The second will contain an array of words which you disallow. The third (optional) parameter can contain a replacement value for the words. If not specified they are replaced with pound signs: #####.

Example:

```
$disallowed = array('darn', 'shucks', 'golly', 'phooey');
$string = word_censor($string, $disallowed, 'Beep!');
```

highlight_code()

highlight_code (*\$str*)

- **\$str** (*string*) – Input string

string

Colorizes a string of code (PHP, HTML, etc.). Example:

```
$string = highlight_code($string);
```

The function uses PHP's `highlight_string()` function, so the colors used are the ones specified in your `php.ini` file.

highlight_phrase()

highlight_phrase (*\$str*, *\$phrase*, *\$tag_open* = '', *\$tag_close* = '')

- **\$str** (*string*) – Input string
- **\$phrase** (*string*) – Phrase to highlight
- **\$tag_open** (*string*) – Opening tag used for the highlight
- **\$tag_close** (*string*) – Closing tag for the highlight

string

Will highlight a phrase within a text string. The first parameter will contain the original string, the second will contain the phrase you wish to highlight. The third and fourth parameters will contain the opening/closing HTML tags you would like the phrase wrapped in.

Example:

```
$string = "Here is a nice text string about nothing in particular.";
echo highlight_phrase($string, "nice text", '<span style="color:#990000;">', '</span>');
```

The above code prints:

```
Here is a <span style="color:#990000;">nice text</span> string about nothing in particular.
```

word_wrap()

word_wrap (*\$str*, *\$charlim* = 76)

- **\$str** (*string*) – Input string
- **\$charlim** (*int*) – Character limit

string

Wraps text at the specified *character* count while maintaining complete words.

Example:

```
$string = "Here is a simple string of text that will help us demonstrate this function.";
echo word_wrap($string, 25);

// Would produce: Here is a simple string of text that will help us demonstrate this function
```

ellipsesize()

ellipsesize (*\$str*, *\$max_length*, *\$position* = 1, *\$ellipsis* = '…')

- **\$str** (*string*) – Input string
- **\$max_length** (*int*) – String length limit
- **\$position** (*mixed*) – Position to split at (int or float)
- **\$ellipsis** (*string*) – What to use as the ellipsis character

string

This function will strip tags from a string, split it at a defined maximum length, and insert an ellipsis.

The first parameter is the string to ellipsesize, the second is the number of characters in the final string. The third parameter is where in the string the ellipsis should appear from 0 - 1, left to right. For example, a value of 1 will place the ellipsis at the right of the string, .5 in the middle, and 0 at the left.

An optional forth parameter is the kind of ellipsis. By default, … will be inserted.

Example:

```
$str = 'this_string_is_entirely_too_long_and_might_break_my_design.jpg';
echo ellipsesize($str, 32, .5);
```

Produces:

```
this_string_is_e&hellip;ak_my_design.jpg
```

10.14.19 Typography Helper

The Typography Helper file contains functions that help you format text in semantically relevant ways.

Page Contents

- Typography Helper
 - Loading this Helper
 - `auto_typography()`
 - `nl2br_except_pre()`
 - `entity_decode()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('typography');
```

The following functions are available:

`auto_typography()`

`auto_typography` (*\$str*, *\$reduce_linebreaks* = *FALSE*)

- **`$str`** (*string*) – Input string
- **`$reduce_linebreaks`** (*bool*) – Whether to reduce multiple instances of double newlines to two

string

Formats text so that it is semantically and typographically correct HTML.

This function is an alias for `CI_Typography::auto_typography`. For more info, please see the *Typography Library* documentation.

Usage example:

```
$string = auto_typography($string);
```

: Typographic formatting can be processor intensive, particularly if you have a lot of content being formatted. If you choose to use this function you may want to consider *caching* [<../general/caching>](#) your pages.

`nl2br_except_pre()`

`nl2br_except_pre` (*\$str*)

- **`$str`** (*string*) – Input string

string

Converts newlines to
 tags unless they appear within <pre> tags. This function is identical to the native PHP `nl2br()` function, except that it ignores <pre> tags.

Usage example:

```
$string = nl2br_except_pre($string);
```

entity_decode()

entity_decode (*\$str*, *\$charset* = *NULL*)

- **\$str** (*string*) – Input string
- **\$charset** (*string*) – Character set

string

This function is an alias for `CI_Security::entity_decode()`. For more info, please see the *Security Library* documentation.

10.14.20 URL Helper

The URL Helper file contains functions that assist in working with URLs.

Page Contents

- URL Helper
 - Loading this Helper
 - `site_url()`
 - `base_url()`
 - `current_url()`
 - `uri_string()`
 - `index_page()`
 - `anchor()`
 - `anchor_popup()`
 - `mailto()`
 - `safe_mailto()`
 - `auto_link()`
 - `url_title()`
 - * `prep_url()`
 - `redirect()`

Loading this Helper

This helper is loaded using the following code:

```
$this->load->helper('url');
```

The following functions are available:

site_url()

site_url (*\$uri* = '', *\$protocol* = NULL)

- **\$uri** (*string*) – URI string
- **\$protocol** (*string*) – Protocol, e.g. 'http' or 'https'

string

Returns your site URL, as specified in your config file. The `index.php` file (or whatever you have set as your site **index_page** in your config file) will be added to the URL, as will any URI segments you pass to the function, plus the **url_suffix** as set in your config file.

You are encouraged to use this function any time you need to generate a local URL so that your pages become more portable in the event your URL changes.

Segments can be optionally passed to the function as a string or an array. Here is a string example:

```
echo site_url('news/local/123');
```

The above example would return something like: *http://example.com/index.php/news/local/123*

Here is an example of segments passed as an array:

```
$segments = array('news', 'local', '123');
echo site_url($segments);
```

This function is an alias for `CI_Config::site_url()`. For more info, please see the *Config Library* documentation.

base_url()

base_url (*\$uri* = '', *\$protocol* = NULL)

- **\$uri** (*string*) – URI string
- **\$protocol** (*string*) – Protocol, e.g. 'http' or 'https'

string

Returns your site base URL, as specified in your config file. Example:

```
echo base_url();
```

This function returns the same thing as `site_url()`, without the *index_page* or *url_suffix* being appended.

Also like `site_url()`, you can supply segments as a string or an array. Here is a string example:

```
echo base_url("blog/post/123");
```

The above example would return something like: *http://example.com/blog/post/123*

This is useful because unlike `site_url()`, you can supply a string to a file, such as an image or stylesheet. For example:

```
echo base_url("images/icons/edit.png");
```

This would give you something like: *http://example.com/images/icons/edit.png*

This function is an alias for `CI_Config::base_url()`. For more info, please see the *Config Library* documentation.

current_url()

current_url()

string

Returns the full URL (including segments) of the page being currently viewed.

: Calling this function is the same as doing this: `|| site_url(uri_string());`

uri_string()

uri_string()

string

Returns the URI segments of any page that contains this function. For example, if your URL was this:

http://some-site.com/blog/comments/123

The function would return:

blog/comments/123

This function is an alias for `CI_Config::uri_string()`. For more info, please see the *Config Library* documentation.

index_page()

index_page()

string

Returns your site **index_page**, as specified in your config file. Example:

```
echo index_page();
```

anchor()

anchor() (*\$uri* = '', *\$title* = '', *\$attributes* = '')

- **\$uri** (*string*) – URI string
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Creates a standard HTML anchor link based on your local site URL.

The first parameter can contain any segments you wish appended to the URL. As with the `site_url()` function above, segments can be a string or an array.

: If you are building links that are internal to your application do not include the base URL (<http://...>). This will be added automatically from the information specified in your config file. Include only the URI segments you wish appended to the URL.

The second segment is the text you would like the link to say. If you leave it blank, the URL will be used.

The third parameter can contain a list of attributes you would like added to the link. The attributes can be a simple string or an associative array.

Here are some examples:

```
echo anchor('news/local/123', 'My News', 'title="News title"');
// Prints: <a href="http://example.com/index.php/news/local/123" title="News title">My News</a>

echo anchor('news/local/123', 'My News', array('title' => 'The best news!'));
// Prints: <a href="http://example.com/index.php/news/local/123" title="The best news!">My News</a>

echo anchor('', 'Click here');
// Prints: <a href="http://example.com">Click Here</a>
```

anchor_popup()

anchor_popup (*\$uri* = '', *\$title* = '', *\$attributes* = FALSE)

- **\$uri** (*string*) – URI string
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Nearly identical to the `:php:func:anchor()` function except that it opens the URL in a new window. You can specify JavaScript window attributes in the third parameter to control how the window is opened. If the third parameter is not set it will simply open a new window with your own browser settings.

Here is an example with attributes:

```
$atts = array(
    'width'      => 800,
    'height'     => 600,
    'scrollbars' => 'yes',
    'status'     => 'yes',
    'resizable'  => 'yes',
    'screenx'    => 0,
    'screeny'    => 0,
    'window_name' => '_blank'
);

echo anchor_popup('news/local/123', 'Click Me!', $atts);
```

: The above attributes are the function defaults so you only need to set the ones that are different from what you

need. If you want the function to use all of its defaults simply pass an empty array in the third parameter: `|| echo anchor_popup('news/local/123', 'Click Me!', array());`

: The **window_name** is not really an attribute, but an argument to the JavaScript `window.open()` `<http://www.w3schools.com/jsref/met_win_open.asp>` method, which accepts either a window name or a window target.

: Any other attribute than the listed above will be parsed as an HTML attribute to the anchor tag.

mailto()

mailto (*\$email*, *\$title* = '', *\$attributes* = '')

- **\$email** (*string*) – E-mail address
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Creates a standard HTML e-mail link. Usage example:

```
echo mailto('me@my-site.com', 'Click Here to Contact Me');
```

As with the `anchor()` tab above, you can set attributes using the third parameter:

```
$attributes = array('title' => 'Mail me');  
echo mailto('me@my-site.com', 'Contact Me', $attributes);
```

safe_mailto()

safe_mailto (*\$email*, *\$title* = '', *\$attributes* = '')

- **\$email** (*string*) – E-mail address
- **\$title** (*string*) – Anchor title
- **\$attributes** (*mixed*) – HTML attributes

string

Identical to the `mailto()` function except it writes an obfuscated version of the *mailto* tag using ordinal numbers written with JavaScript to help prevent the e-mail address from being harvested by spam bots.

auto_link()

auto_link (*\$str*, *\$type* = 'both', *\$popup* = FALSE)

- **\$str** (*string*) – Input string
- **\$type** (*string*) – Link type ('email', 'url' or 'both')

- **\$popup** (*bool*) – Whether to create popup links

string

Automatically turns URLs and e-mail addresses contained in a string into links. Example:

```
$string = auto_link($string);
```

The second parameter determines whether URLs and e-mails are converted or just one or the other. Default behavior is both if the parameter is not specified. E-mail links are encoded as `safe_mailto()` as shown above.

Converts only URLs:

```
$string = auto_link($string, 'url');
```

Converts only e-mail addresses:

```
$string = auto_link($string, 'email');
```

The third parameter determines whether links are shown in a new window. The value can be TRUE or FALSE (boolean):

```
$string = auto_link($string, 'both', TRUE);
```

url_title()

url_title (*\$str*, *\$separator* = '-', *\$lowercase* = FALSE)

- **\$str** (*string*) – Input string
- **\$separator** (*string*) – Word separator
- **\$lowercase** (*string*) – Whether to transform the output string to lower-case

string

Takes a string as input and creates a human-friendly URL string. This is useful if, for example, you have a blog in which you'd like to use the title of your entries in the URL. Example:

```
$title = "What's wrong with CSS?";
$url_title = url_title($title);
// Produces: Whats-wrong-with-CSS
```

The second parameter determines the word delimiter. By default dashes are used. Preferred options are: - (dash) or _ (underscore)

Example:

```
$title = "What's wrong with CSS?";
$url_title = url_title($title, 'underscore');
// Produces: Whats_wrong_with_CSS
```

: Old usage of 'dash' and 'underscore' as the second parameter is DEPRECATED.

The third parameter determines whether or not lowercase characters are forced. By default they are not. Options are boolean TRUE/FALSE.

Example:

```
$title = "What's wrong with CSS?";
$url_title = url_title($title, 'underscore', TRUE);
// Produces: whats_wrong_with_css
```

prep_url()

prep_url (\$str = '')

- **\$str** (*string*) – URL string

string

This function will add <http://> in the event that a protocol prefix is missing from a URL.

Pass the URL string to the function like this:

```
$url = prep_url('example.com');
```

redirect()

redirect (\$uri = '', \$method = 'auto', \$code = NULL)

- **\$uri** (*string*) – URI string
- **\$method** (*string*) – Redirect method ('auto', 'location' or 'refresh')
- **\$code** (*string*) – HTTP Response code (usually 302 or 303)

void

Does a “header redirect” to the URI specified. If you specify the full site URL that link will be built, but for local links simply providing the URI segments to the controller you want to direct to will create the link. The function will build the URL based on your config file values.

The optional second parameter allows you to force a particular redirection method. The available methods are **auto**, **location** and **refresh**, with location being faster but less reliable on IIS servers. The default is **auto**, which will attempt to intelligently choose the method based on the server environment.

The optional third parameter allows you to send a specific HTTP Response Code - this could be used for example to create 301 redirects for search engine purposes. The default Response Code is 302. The third parameter is *only* available with **location** redirects, and not *refresh*. Examples:

```
if ($logged_in == FALSE)
{
    redirect('/login/form/');
}

// with 301 redirect
redirect('/article/13', 'location', 301);
```

: In order for this function to work it must be used before anything is outputted to the browser since it utilizes server headers.

: For very fine grained control over headers, you should use the *Output Library* </libraries/output> `set_header()` method.

: To IIS users: if you hide the *Server* HTTP header, the *auto* method won't detect IIS, in that case it is advised you explicitly use the **refresh** method.

: When the **location** method is used, an HTTP status code of 303 will *automatically* be selected when the page is currently accessed via POST and HTTP/1.1 is used.

: This function will terminate script execution.

10.14.21 XML Helper

The XML Helper file contains functions that assist in working with XML data.

Page Contents

- XML Helper
 - Loading this Helper
 - `xml_convert()`

Loading this Helper

This helper is loaded using the following code

```
$this->load->helper('xml');
```

The following functions are available:

`xml_convert()`

Takes a string as input and converts the following reserved XML characters to entities:

- Ampersands: `&`
- Less than and greater than characters: `<` `>`
- Single and double quotes: `'` `"`
- Dashes: `-`

This function ignores ampersands if they are part of existing character entities. Example

```
$string = xml_convert($string);
```

10.15 The Database Class

CodeIgniter comes with a full-featured and very fast abstracted database class that supports both traditional structures and Query Builder patterns. The database functions offer clear, simple syntax.

10.15.1 Database Quick Start: Example Code

The following page contains example code showing how the database class is used. For complete details please read the individual pages describing each function.

Initializing the Database Class

The following code loads and initializes the database class based on your *configuration* settings:

```
$this->load->database();
```

Once loaded the class is ready to be used as described below.

Note: If all your pages require database access you can connect automatically. See the *connecting* page for details.

Standard Query With Multiple Results (Object Version)

```
$query = $this->db->query('SELECT name, title, email FROM my_table');

foreach ($query->result() as $row)
{
    echo $row->title;
    echo $row->name;
    echo $row->email;
}

echo 'Total Results: ' . $query->num_rows();
```

The above result() function returns an array of **objects**. Example: \$row->title

Standard Query With Multiple Results (Array Version)

```
$query = $this->db->query('SELECT name, title, email FROM my_table');

foreach ($query->result_array() as $row)
{
    echo $row['title'];
    echo $row['name'];
    echo $row['email'];
}
```

The above result_array() function returns an array of standard array indexes. Example: \$row['title']

Testing for Results

If you run queries that might **not** produce a result, you are encouraged to test for a result first using the num_rows() function:

```
$query = $this->db->query("YOUR QUERY");
if ($query->num_rows() > 0)
{
    foreach ($query->result() as $row)
    {
        echo $row->title;
    }
}
```

```

        echo $row->name;
        echo $row->body;
    }
}

```

Standard Query With Single Result

```

$query = $this->db->query('SELECT name FROM my_table LIMIT 1');
$row = $query->row();
echo $row->name;

```

The above `row()` function returns an **object**. Example: `$row->name`

Standard Query With Single Result (Array version)

```

$query = $this->db->query('SELECT name FROM my_table LIMIT 1');
$row = $query->row_array();
echo $row['name'];

```

The above `row_array()` function returns an **array**. Example: `$row['name']`

Standard Insert

```

$sql = "INSERT INTO mytable (title, name) VALUES (". $this->db->escape($title).", ". $this->db->escape(
$this->db->query($sql);
echo $this->db->affected_rows();

```

Query Builder Query

The *Query Builder Pattern* gives you a simplified means of retrieving data:

```

$query = $this->db->get('table_name');

foreach ($query->result() as $row)
{
    echo $row->title;
}

```

The above `get()` function retrieves all the results from the supplied table. The *Query Builder* class contains a full compliment of functions for working with data.

Query Builder Insert

```

$data = array(
    'title' => $title,
    'name' => $name,
    'date' => $date
);

$this->db->insert('mytable', $data); // Produces: INSERT INTO mytable (title, name, date) VALUES (

```

10.15.2 Database Configuration

CodeIgniter has a config file that lets you store your database connection values (username, password, database name, etc.). The config file is located at `application/config/database.php`. You can also set database connection values for specific *environments* by placing **database.php** in the respective environment config folder.

The config settings are stored in a multi-dimensional array with this prototype:

```
$db['default'] = array(
    'dsn'       => '',
    'hostname'  => 'localhost',
    'username'  => 'root',
    'password'  => '',
    'database'  => 'database_name',
    'dbdriver'  => 'mysqli',
    'dbprefix'  => '',
    'pconnect'  => TRUE,
    'db_debug'  => TRUE,
    'cache_on'  => FALSE,
    'cachedir'  => '',
    'char_set'  => 'utf8',
    'dbcollat'  => 'utf8_general_ci',
    'swap_pre'  => '',
    'autoinit'  => TRUE,
    'encrypt'   => FALSE,
    'compress'  => FALSE,
    'stricton'  => FALSE,
    'failover'  => array()
);
```

Some database drivers (such as PDO, PostgreSQL, Oracle, ODBC) might require a full DSN string to be provided. If that is the case, you should use the 'dsn' configuration setting, as if you're using the driver's underlying native PHP extension, like this:

```
// PDO
$db['default']['dsn'] = 'pgsql:host=localhost;port=5432;dbname=database_name';

// Oracle
$db['default']['dsn'] = '//localhost/XE';
```

: If you do not specify a DSN string for a driver that requires it, CodeIgniter will try to build it with the rest of the provided settings.

: If you provide a DSN string and it is missing some valid settings (e.g. the database character set), which are present in the rest of the configuration fields, CodeIgniter will append them.

You can also specify failovers for the situation when the main connection cannot connect for some reason. These failovers can be specified by setting the failover for a connection like this:

```
$db['default']['failover'] = array(
    array(
        'hostname' => 'localhost1',
        'username' => '',
        'password' => '',
        'database' => '',
        'dbdriver'  => 'mysqli',
        'dbprefix'  => ''
```

```

        'pconnect' => TRUE,
        'db_debug' => TRUE,
        'cache_on' => FALSE,
        'cachedir' => '',
        'char_set' => 'utf8',
        'dbcollat' => 'utf8_general_ci',
        'swap_pre' => '',
        'autoinit' => TRUE,
        'encrypt' => FALSE,
        'compress' => FALSE,
        'stricton' => FALSE
    ),
    array(
        'hostname' => 'localhost2',
        'username' => '',
        'password' => '',
        'database' => '',
        'dbdriver' => 'mysqli',
        'dbprefix' => '',
        'pconnect' => TRUE,
        'db_debug' => TRUE,
        'cache_on' => FALSE,
        'cachedir' => '',
        'char_set' => 'utf8',
        'dbcollat' => 'utf8_general_ci',
        'swap_pre' => '',
        'autoinit' => TRUE,
        'encrypt' => FALSE,
        'compress' => FALSE,
        'stricton' => FALSE
    )
);

```

You can specify as many failovers as you like.

The reason we use a multi-dimensional array rather than a more simple one is to permit you to optionally store multiple sets of connection values. If, for example, you run multiple environments (development, production, test, etc.) under a single installation, you can set up a connection group for each, then switch between groups as needed. For example, to set up a “test” environment you would do this:

```

$db['test'] = array(
    'dsn' => '',
    'hostname' => 'localhost',
    'username' => 'root',
    'password' => '',
    'database' => 'database_name',
    'dbdriver' => 'mysqli',
    'dbprefix' => '',
    'pconnect' => TRUE,
    'db_debug' => TRUE,
    'cache_on' => FALSE,
    'cachedir' => '',
    'char_set' => 'utf8',
    'dbcollat' => 'utf8_general_ci',
    'swap_pre' => '',
    'autoinit' => TRUE,
    'compress' => FALSE,
    'encrypt' => FALSE,
    'stricton' => FALSE,

```

```
        'failover' => array()  
    );
```

Then, to globally tell the system to use that group you would set this variable located in the config file:

```
$active_group = 'test';
```

: The name 'test' is arbitrary. It can be anything you want. By default we've used the word "default" for the primary connection, but it too can be renamed to something more relevant to your project.

Query Builder

The *Query Builder Class* is globally enabled or disabled by setting the `$query_builder` variable in the database configuration file to TRUE/FALSE (boolean). If you are not using the query builder class, setting it to FALSE will utilize fewer resources when the database classes are initialized.

```
$query_builder = TRUE;
```

: that some CodeIgniter classes such as Sessions require Query Builder to be enabled to access certain functionality.

Explanation of Values:

Name Config	Description
dsn	The DSN connect string (an all-in-one configuration sequence).
hostname	The hostname of your database server. Often this is 'localhost'.
username	The username used to connect to the database.
password	The password used to connect to the database.
database	The name of the database you want to connect to.
dbdriver	The database type. ie: mysqli, postgres, odbc, etc. Must be specified in lower case.
dbprefix	An optional table prefix which will added to the table name when running <i>Query Builder</i> <code><query_builder></code> queries. This permits multiple CodeIgniter installations to share one database.
pconnect	TRUE/FALSE (boolean) - Whether to use a persistent connection.
db_debug	TRUE/FALSE (boolean) - Whether database errors should be displayed.
cache_on	TRUE/FALSE (boolean) - Whether database query caching is enabled, see also <i>Database Caching Class</i> .
cachedir	The absolute server path to your database query cache directory.
char_set	The character set used in communicating with the database.
dbcollat	The character collation used in communicating with the database
	<hr/> : Only used in the 'mysql' and 'mysqli' drivers. <hr/>
swap_pre	A default table prefix that should be swapped with dbprefix. This is useful for distributed applications where you might run manually written queries, and need the prefix to still be customizable by the end user.
autoinit	Whether or not to automatically connect to the database when the library loads. If set to false, the connection will take place prior to executing the first query.
schema	The database schema, defaults to 'public'. Used by PostgreSQL and ODBC drivers.
encrypt	Whether or not to use an encrypted connection.
compress	Whether or not to use client compression (MySQL only).
stricton	TRUE/FALSE (boolean) - Whether to force "Strict Mode" connections, good for ensuring strict SQL while developing an application.
port	The database port number. To use this value you have to add a line to the database config array. <pre>\$db['default']['port'] = 5432;</pre>

: Depending on what database platform you are using (MySQL, PostgreSQL, etc.) not all values will be needed. For example, when using SQLite you will not need to supply a username or password, and the database name will be the path to your database file. The information above assumes you are using MySQL.

10.15.3 Connecting to your Database

There are two ways to connect to a database:

Automatically Connecting

The “auto connect” feature will load and instantiate the database class with every page load. To enable “auto connecting”, add the word database to the library array, as indicated in the following file:

application/config/autoload.php

Manually Connecting

If only some of your pages require database connectivity you can manually connect to your database by adding this line of code in any function where it is needed, or in your class constructor to make the database available globally in that class.

```
$this->load->database();
```

If the above function does **not** contain any information in the first parameter it will connect to the group specified in your database config file. For most people, this is the preferred method of use.

Available Parameters

1. The database connection values, passed either as an array or a DSN string.
2. TRUE/FALSE (boolean). Whether to return the connection ID (see Connecting to Multiple Databases below).
3. TRUE/FALSE (boolean). Whether to enable the Query Builder class. Set to TRUE by default.

Manually Connecting to a Database

The first parameter of this function can **optionally** be used to specify a particular database group from your config file, or you can even submit connection values for a database that is not specified in your config file. Examples:

To choose a specific group from your config file you can do this:

```
$this->load->database('group_name');
```

Where group_name is the name of the connection group from your config file.

To connect manually to a desired database you can pass an array of values:

```
$config['hostname'] = 'localhost';
$config['username'] = 'myusername';
$config['password'] = 'mypassword';
$config['database'] = 'mydatabase';
$config['dbdriver'] = 'mysqli';
$config['dbprefix'] = '';
$config['pconnect'] = FALSE;
$config['db_debug'] = TRUE;
$config['cache_on'] = FALSE;
$config['cachedir'] = '';
```

```
$config['char_set'] = 'utf8';
$config['dbcollat'] = 'utf8_general_ci';
$this->load->database($config);
```

For information on each of these values please see the *configuration page*.

: For the PDO driver, you should use the `$config['dsn']` setting instead of 'hostname' and 'database':

```
$config['dsn'] = 'mysql:host=localhost;dbname=mydatabase';
```

Or you can submit your database values as a Data Source Name. DSNs must have this prototype:

```
$dsn = 'dbdriver://username:password@hostname/database';
$this->load->database($dsn);
```

To override default config values when connecting with a DSN string, add the config variables as a query string.

```
$dsn = 'dbdriver://username:password@hostname/database?char_set=utf8&dbcollat=utf8_general_ci&cache_';
$this->load->database($dsn);
```

Connecting to Multiple Databases

If you need to connect to more than one database simultaneously you can do so as follows:

```
$DB1 = $this->load->database('group_one', TRUE);
$DB2 = $this->load->database('group_two', TRUE);
```

Note: Change the words “group_one” and “group_two” to the specific group names you are connecting to (or you can pass the connection values as indicated above).

By setting the second parameter to TRUE (boolean) the function will return the database object.

: When you connect this way, you will use your object name to issue commands rather than the syntax used throughout this guide. In other words, rather than issuing commands with:

```
$this->db->query();
$this->db->result();
etc...
```

You will instead use:

```
$DB1->query();
$DB1->result();
etc...
```

: You don't need to create separate database configurations if you only need to use a different database on the same

connection. You can switch to a different database when you need to, like this:

```
$this->db->db_select($database2_name);
```

Reconnecting / Keeping the Connection Alive

If the database server's idle timeout is exceeded while you're doing some heavy PHP lifting (processing an image, for instance), you should consider pinging the server by using the `reconnect()` method before sending further queries, which can gracefully keep the connection alive or re-establish it.

```
$this->db->reconnect();
```

Manually closing the Connection

While CodeIgniter intelligently takes care of closing your database connections, you can explicitly close the connection.

```
$this->db->close();
```

10.15.4 Queries

`$this->db->query();`

To submit a query, use the following function:

```
$this->db->query('YOUR QUERY HERE');
```

The `query()` function returns a database result **object** when “read” type queries are run, which you can use to *show your results*. When “write” type queries are run it simply returns TRUE or FALSE depending on success or failure. When retrieving data you will typically assign the query to your own variable, like this:

```
$query = $this->db->query('YOUR QUERY HERE');
```

`$this->db->simple_query();`

This is a simplified version of the `$this->db->query()` method. It DOES NOT return a database result set, nor does it set the query timer, or compile bind data, or store your query for debugging. It simply lets you submit a query. Most users will rarely use this function.

It returns whatever the database drivers' “execute” function returns. That typically is TRUE/FALSE on success or failure for write type queries such as INSERT, DELETE or UPDATE statements (which is what it really should be used for) and a resource/object on success for queries with fetchable results.

```
if ($this->db->simple_query('YOUR QUERY'))
{
    echo "Success!";
}
else
{

```

```
        echo "Query failed!";
    }
}
```

: PostgreSQL's `pg_exec()` function always returns a resource on success, even for write type queries. So take that in mind if you're looking for a boolean value.

Working with Database prefixes manually

If you have configured a database prefix and would like to prepend it to a table name for use in a native SQL query for example, then you can use the following:

```
$this->db->dbprefix('tablename'); // outputs prefix_tablename
```

If for any reason you would like to change the prefix programmatically without needing to create a new connection, you can use this method:

```
$this->db->set_dbprefix('newprefix');
$this->db->dbprefix('tablename'); // outputs newprefix_tablename
```

Protecting identifiers

In many databases it is advisable to protect table and field names - for example with backticks in MySQL. **Query Builder queries are automatically protected**, however if you need to manually protect an identifier you can use:

```
$this->db->protect_identifiers('table_name');
```

This function will also add a table prefix to your table, assuming you have a prefix specified in your database config file. To enable the prefixing set `TRUE` (boolean) via the second parameter:

```
$this->db->protect_identifiers('table_name', TRUE);
```

Escaping Queries

It's a very good security practice to escape your data before submitting it into your database. CodeIgniter has three methods that help you do this:

1. **`$this->db->escape()`** This function determines the data type so that it can escape only string data. It also automatically adds single quotes around the data so you don't have to:

```
$sql = "INSERT INTO table (title) VALUES('".$this->db->escape($title).")";
```

2. **`$this->db->escape_str()`** This function escapes the data passed to it, regardless of type. Most of the time you'll use the above function rather than this one. Use the function like this:

```
$sql = "INSERT INTO table (title) VALUES('".$this->db->escape_str($title).")";
```

3. **`$this->db->escape_like_str()`** This method should be used when strings are to be used in `LIKE` conditions so that `LIKE` wildcards (`'%'`, `'_'`) in the string are also properly escaped.

```
$search = '20% raise'; $sql = "SELECT id FROM table WHERE column LIKE '%" . $this->db->escape_like_str($search) . "%'";
```

Query Bindings

Bindings enable you to simplify your query syntax by letting the system put the queries together for you. Consider the following example:

```
$sql = "SELECT * FROM some_table WHERE id = ? AND status = ? AND author = ?";
$this->db->query($sql, array(3, 'live', 'Rick'));
```

The question marks in the query are automatically replaced with the values in the array in the second parameter of the query function.

The secondary benefit of using binds is that the values are automatically escaped, producing safer queries. You don't have to remember to manually escape data; the engine does it automatically for you.

Handling Errors

`$this->db->error();`

If you need to get the last error that has occurred, the `error()` method will return an array containing its code and message. Here's a quick example:

```
if ( ! $this->db->simple_query('SELECT `example_field` FROM `example_table`'))
{
    $error = $this->db->error(); // Has keys 'code' and 'message'
}
```

10.15.5 Generating Query Results

There are several ways to generate query results:

`result()`

This function returns the query result as an array of **objects**, or an **empty array** on failure. Typically you'll use this in a `foreach` loop, like this:

```
$query = $this->db->query("YOUR QUERY");

foreach ($query->result() as $row)
{
    echo $row->title;
    echo $row->name;
    echo $row->body;
}
```

The above function is an alias of `result_object()`.

If you run queries that might **not** produce a result, you are encouraged to test the result first:

```
$query = $this->db->query("YOUR QUERY");

if ($query->num_rows() > 0)
{
    foreach ($query->result() as $row)
    {
        echo $row->title;
    }
}
```

```

        echo $row->name;
        echo $row->body;
    }
}

```

You can also pass a string to `result()` which represents a class to instantiate for each result object (note: this class must be loaded)

```

$query = $this->db->query("SELECT * FROM users;");

foreach ($query->result('User') as $user)
{
    echo $user->name; // call attributes
    echo $user->reverse_name(); // or methods defined on the 'User' class
}

```

result_array()

This function returns the query result as a pure array, or an empty array when no result is produced. Typically you'll use this in a `foreach` loop, like this:

```

$query = $this->db->query("YOUR QUERY");

foreach ($query->result_array() as $row)
{
    echo $row['title'];
    echo $row['name'];
    echo $row['body'];
}

```

row()

This function returns a single result row. If your query has more than one row, it returns only the first row. The result is returned as an **object**. Here's a usage example:

```

$query = $this->db->query("YOUR QUERY");

if ($query->num_rows() > 0)
{
    $row = $query->row();

    echo $row->title;
    echo $row->name;
    echo $row->body;
}

```

If you want a specific row returned you can submit the row number as a digit in the first parameter:

```

$row = $query->row(5);

```

You can also add a second String parameter, which is the name of a class to instantiate the row with:

```

$query = $this->db->query("SELECT * FROM users LIMIT 1;");
$row = $query->row(0, 'User');

echo $row->name; // call attributes
echo $row->reverse_name(); // or methods defined on the 'User' class

```

row_array()

Identical to the above `row()` function, except it returns an array. Example:

```
$query = $this->db->query("YOUR QUERY");

if ($query->num_rows() > 0)
{
    $row = $query->row_array();

    echo $row['title'];
    echo $row['name'];
    echo $row['body'];
}
```

If you want a specific row returned you can submit the row number as a digit in the first parameter:

```
$row = $query->row_array(5);
```

In addition, you can walk forward/backwards/first/last through your results using these variations:

```
$row = $query->first_row()
$row = $query->last_row()
$row = $query->next_row()
$row = $query->previous_row()
```

By default they return an object unless you put the word “array” in the parameter:

```
$row = $query->first_row('array')
$row = $query->last_row('array')
$row = $query->next_row('array')
$row = $query->previous_row('array')
```

: all the functions above will load the whole result into memory (prefetching) use `unbuffered_row()` for processing large result sets.

unbuffered_row()

This method returns a single result row without prefetching the whole result in memory as `row()` does. If your query has more than one row, it returns the current row and moves the internal data pointer ahead.

```
$query = $this->db->query("YOUR QUERY");

while ($row = $query->unbuffered_row())
{
    echo $row->title;
    echo $row->name;
    echo $row->body;
}
```

You can optionally pass ‘object’ (default) or ‘array’ in order to specify the returned value’s type:

```
$query->unbuffered_row();           // object
$query->unbuffered_row('object');   // object
$query->unbuffered_row('array');    // associative array
```

Result Helper Functions

\$query->num_rows()

The number of rows returned by the query. Note: In this example, \$query is the variable that the query result object is assigned to:

```
$query = $this->db->query('SELECT * FROM my_table');

echo $query->num_rows();
```

: Not all database drivers have a native way of getting the total number of rows for a result set. When this is the case, all of the data is prefetched and count() is manually called on the resulting array in order to achieve the same functionality.

\$query->num_fields()

The number of FIELDS (columns) returned by the query. Make sure to call the function using your query result object:

```
$query = $this->db->query('SELECT * FROM my_table');

echo $query->num_fields();
```

\$query->free_result()

It frees the memory associated with the result and deletes the result resource ID. Normally PHP frees its memory automatically at the end of script execution. However, if you are running a lot of queries in a particular script you might want to free the result after each query result has been generated in order to cut down on memory consumptions. Example:

```
$query = $this->db->query('SELECT title FROM my_table');

foreach ($query->result() as $row)
{
    echo $row->title;
}
$query->free_result(); // The $query result object will no longer be available

$query2 = $this->db->query('SELECT name FROM some_table');

$row = $query2->row();
echo $row->name;
$query2->free_result(); // The $query2 result object will no longer be available
```

data_seek()

This method sets the internal pointer for the next result row to be fetched. It is only useful in combination with unbuffered_row().

It accepts a positive integer value, which defaults to 0 and returns TRUE on success or FALSE on failure.

```
$query = $this->db->query('SELECT `field_name` FROM `table_name`');  
$query->data_seek(5); // Skip the first 5 rows  
$row = $query->unbuffered_row();
```

: Not all database drivers support this feature and will return FALSE. Most notably - you won't be able to use it with PDO.

10.15.6 Query Helper Functions

`$this->db->insert_id()`

The insert ID number when performing database inserts.

: If using the PDO driver with PostgreSQL, or using the Interbase driver, this function requires a \$name parameter, which specifies the appropriate sequence to check for the insert id.

`$this->db->affected_rows()`

Displays the number of affected rows, when doing “write” type queries (insert, update, etc.).

: In MySQL “DELETE FROM TABLE” returns 0 affected rows. The database class has a small hack that allows it to return the correct number of affected rows. By default this hack is enabled but it can be turned off in the database driver file.

`$this->db->count_all();`

Permits you to determine the number of rows in a particular table. Submit the table name in the first parameter. Example:

```
echo $this->db->count_all('my_table');  
  
// Produces an integer, like 25
```

`$this->db->platform()`

Outputs the database platform you are running (MySQL, MS SQL, Postgres, etc...):

```
echo $this->db->platform();
```

`$this->db->version()`

Outputs the database version you are running:

```
echo $this->db->version();
```

`$this->db->last_query();`

Returns the last query that was run (the query string, not the result). Example:

```
$str = $this->db->last_query();

// Produces:  SELECT * FROM sometable....
```

The following two functions help simplify the process of writing database INSERTs and UPDATES.

`$this->db->insert_string();`

This function simplifies the process of writing database inserts. It returns a correctly formatted SQL insert string. Example:

```
$data = array('name' => $name, 'email' => $email, 'url' => $url);

$str = $this->db->insert_string('table_name', $data);
```

The first parameter is the table name, the second is an associative array with the data to be inserted. The above example produces:

```
INSERT INTO table_name (name, email, url) VALUES ('Rick', 'rick@example.com', 'example.com')
```

: Values are automatically escaped, producing safer queries.

`$this->db->update_string();`

This function simplifies the process of writing database updates. It returns a correctly formatted SQL update string. Example:

```
$data = array('name' => $name, 'email' => $email, 'url' => $url);

$where = "author_id = 1 AND status = 'active'";

$str = $this->db->update_string('table_name', $data, $where);
```

The first parameter is the table name, the second is an associative array with the data to be updated, and the third parameter is the “where” clause. The above example produces:

```
UPDATE table_name SET name = 'Rick', email = 'rick@example.com', url = 'example.com' WHERE author_id
```

: Values are automatically escaped, producing safer queries.

10.15.7 Query Builder Class

CodeIgniter gives you access to a Query Builder class. This pattern allows information to be retrieved, inserted, and updated in your database with minimal scripting. In some cases only one or two lines of code are necessary to perform a database action. CodeIgniter does not require that each database table be its own class file. It instead provides a more simplified interface.

Beyond simplicity, a major benefit to using the Query Builder features is that it allows you to create database independent applications, since the query syntax is generated by each database adapter. It also allows for safer queries, since the values are escaped automatically by the system.

: If you intend to write your own queries you can disable this class in your database config file, allowing the core database library and adapter to utilize fewer resources.

 - * `$this->db->start_cache()`
 - * `$this->db->stop_cache()`
 - * `$this->db->flush_cache()`
 - * `$this->db->reset_query()`

Selecting Data

The following functions allow you to build SQL **SELECT** statements.

`$this->db->get()`

Runs the selection query and returns the result. Can be used by itself to retrieve all records from a table:

```
$query = $this->db->get('mytable'); // Produces: SELECT * FROM mytable
```

The second and third parameters enable you to set a limit and offset clause:

```
$query = $this->db->get('mytable', 10, 20);  
// Produces: SELECT * FROM mytable LIMIT 20, 10 (in MySQL. Other databases have slightly different syntax)
```

You'll notice that the above function is assigned to a variable named `$query`, which can be used to show the results:

```
$query = $this->db->get('mytable');  
  
foreach ($query->result() as $row)  
{  
    echo $row->title;  
}
```

Please visit the *result functions* page for a full discussion regarding result generation.

`$this->db->get_compiled_select()`

Compiles the selection query just like `$this->db->get()` but does not *run* the query. This method simply returns the SQL query as a string.

Example:

```
$sql = $this->db->get_compiled_select('mytable');  
echo $sql;  
  
// Produces string: SELECT * FROM mytable
```

The second parameter enables you to set whether or not the query builder query will be reset (by default it will be reset, just like when using `$this->db->get()`):

```
echo $this->db->limit(10,20)->get_compiled_select('mytable', FALSE);  
// Produces string: SELECT * FROM mytable LIMIT 20, 10  
// (in MySQL. Other databases have slightly different syntax)  
  
echo $this->db->select('title, content, date')->get_compiled_select();  
  
// Produces string: SELECT title, content, date FROM mytable LIMIT 20, 10
```

The key thing to notice in the above example is that the second query did not utilize `$this->db->from()` and did not pass a table name into the first parameter. The reason for this outcome is because the query has not been executed using `$this->db->get()` which resets values or reset directly using `$this->db->reset_query()`.

`$this->db->get_where()`

Identical to the above function except that it permits you to add a “where” clause in the second parameter, instead of using the `db->where()` function:

```
$query = $this->db->get_where('mytable', array('id' => $id), $limit, $offset);
```

Please read the about the where function below for more information.

: `get_where()` was formerly known as `getwhere()`, which has been removed

`$this->db->select()`

Permits you to write the SELECT portion of your query:

```
$this->db->select('title, content, date');
$query = $this->db->get('mytable'); // Produces: SELECT title, content, date FROM mytable
```

: If you are selecting all (*) from a table you do not need to use this function. When omitted, CodeIgniter assumes you wish to SELECT *

`$this->db->select()` accepts an optional second parameter. If you set it to FALSE, CodeIgniter will not try to protect your field or table names with backticks. This is useful if you need a compound select statement.

```
$this->db->select('(SELECT SUM(payments.amount) FROM payments WHERE payments.invoice_id=4) AS amount');
$query = $this->db->get('mytable');
```

`$this->db->select_max()`

Writes a “SELECT MAX(field)” portion for your query. You can optionally include a second parameter to rename the resulting field.

```
$this->db->select_max('age');
$query = $this->db->get('members'); // Produces: SELECT MAX(age) as age FROM members

$this->db->select_max('age', 'member_age');
$query = $this->db->get('members'); // Produces: SELECT MAX(age) as member_age FROM members
```

`$this->db->select_min()`

Writes a “SELECT MIN(field)” portion for your query. As with `select_max()`, You can optionally include a second parameter to rename the resulting field.

```
$this->db->select_min('age');
$query = $this->db->get('members'); // Produces: SELECT MIN(age) as age FROM members
```

`$this->db->select_avg()`

Writes a “SELECT AVG(field)” portion for your query. As with `select_max()`, You can optionally include a second parameter to rename the resulting field.

```
$this->db->select_avg('age');  
$query = $this->db->get('members'); // Produces: SELECT AVG(age) as age FROM members
```

`$this->db->select_sum()`

Writes a “SELECT SUM(field)” portion for your query. As with `select_max()`, You can optionally include a second parameter to rename the resulting field.

```
$this->db->select_sum('age');  
$query = $this->db->get('members'); // Produces: SELECT SUM(age) as age FROM members
```

`$this->db->from()`

Permits you to write the FROM portion of your query:

```
$this->db->select('title, content, date');  
$this->db->from('mytable');  
$query = $this->db->get(); // Produces: SELECT title, content, date FROM mytable
```

: As shown earlier, the FROM portion of your query can be specified in the `$this->db->get()` function, so use whichever method you prefer.

`$this->db->join()`

Permits you to write the JOIN portion of your query:

```
$this->db->select('*');  
$this->db->from('blogs');  
$this->db->join('comments', 'comments.id = blogs.id');  
$query = $this->db->get();  
  
// Produces:  
// SELECT * FROM blogs JOIN comments ON comments.id = blogs.id
```

Multiple function calls can be made if you need several joins in one query.

If you need a specific type of JOIN you can specify it via the third parameter of the function. Options are: left, right, outer, inner, left outer, and right outer.

```
$this->db->join('comments', 'comments.id = blogs.id', 'left');  
// Produces: LEFT JOIN comments ON comments.id = blogs.id
```

`$this->db->where()`

This function enables you to set **WHERE** clauses using one of four methods:

: All values passed to this function are escaped automatically, producing safer queries.

1. Simple key/value method:

```
$this->db->where('name', $name); // Produces: WHERE name = 'Joe'
```

Notice that the equal sign is added for you.

If you use multiple function calls they will be chained together with AND between them:

```
$this->db->where('name', $name);
$this->db->where('title', $title);
$this->db->where('status', $status);
// WHERE name = 'Joe' AND title = 'boss' AND status = 'active'
```

2. **Custom key/value method:** You can include an operator in the first parameter in order to control the comparison:

```
$this->db->where('name !=', $name);
$this->db->where('id <', $id); // Produces: WHERE name != 'Joe' AND id < 45
```

3. **Associative array method:**

```
$array = array('name' => $name, 'title' => $title, 'status' => $status);
$this->db->where($array);
// Produces: WHERE name = 'Joe' AND title = 'boss' AND status = 'active'
```

You can include your own operators using this method as well:

```
$array = array('name !=' => $name, 'id <' => $id, 'date >' => $date);
$this->db->where($array);
```

4. **Custom string:** You can write your own clauses manually:

```
$where = "name='Joe' AND status='boss' OR status='active'";
$this->db->where($where);
```

`$this->db->where()` accepts an optional third parameter. If you set it to FALSE, CodeIgniter will not try to protect your field or table names with backticks.

```
$this->db->where('MATCH (field) AGAINST ("value")', NULL, FALSE);
```

`$this->db->or_where()`

This function is identical to the one above, except that multiple instances are joined by OR:

```
$this->db->where('name !=', $name);
$this->db->or_where('id >', $id); // Produces: WHERE name != 'Joe' OR id > 50
```

: `or_where()` was formerly known as `orwhere()`, which has been removed.

`$this->db->where_in()`

Generates a WHERE field IN ('item', 'item') SQL query joined with AND if appropriate

```
$names = array('Frank', 'Todd', 'James');
$this->db->where_in('username', $names);
// Produces: WHERE username IN ('Frank', 'Todd', 'James')
```

`$this->db->or_where_in()`

Generates a WHERE field IN ('item', 'item') SQL query joined with OR if appropriate

```
$names = array('Frank', 'Todd', 'James');
$this->db->or_where_in('username', $names);
// Produces: OR username IN ('Frank', 'Todd', 'James')
```

`$this->db->where_not_in()`

Generates a WHERE field NOT IN ('item', 'item') SQL query joined with AND if appropriate

```
$names = array('Frank', 'Todd', 'James');
$this->db->where_not_in('username', $names);
// Produces: WHERE username NOT IN ('Frank', 'Todd', 'James')
```

`$this->db->or_where_not_in()`

Generates a WHERE field NOT IN ('item', 'item') SQL query joined with OR if appropriate

```
$names = array('Frank', 'Todd', 'James');
$this->db->or_where_not_in('username', $names);
// Produces: OR username NOT IN ('Frank', 'Todd', 'James')
```

`$this->db->like()`

This method enables you to generate **LIKE** clauses, useful for doing searches.

: All values passed to this method are escaped automatically.

1. Simple key/value method:

```
$this->db->like('title', 'match');
// Produces: WHERE `title` LIKE '%match%' ESCAPE '!'
```

If you use multiple method calls they will be chained together with AND between them:

```
$this->db->like('title', 'match');
$this->db->like('body', 'match');
// WHERE `title` LIKE '%match%' ESCAPE '!' AND `body` LIKE '%match%' ESCAPE '!'
```

If you want to control where the wildcard (%) is placed, you can use an optional third argument. Your options are 'before', 'after' and 'both' (which is the default).

```
$this->db->like('title', 'match', 'before'); // Produces: WHERE `title` LIKE '%match' ESCAPE '!'
$this->db->like('title', 'match', 'after');  // Produces: WHERE `title` LIKE 'match%' ESCAPE '!'
$this->db->like('title', 'match', 'both');   // Produces: WHERE `title` LIKE '%match%' ESCAPE '!'
```

2. Associative array method:

```
$array = array('title' => $match, 'page1' => $match, 'page2' => $match);
$this->db->like($array);
// WHERE `title` LIKE '%match%' ESCAPE '!' AND `page1` LIKE '%match%' ESCAPE '!' AND `page2` LIKE '%match%' ESCAPE '!'
```

`$this->db->or_like()`

This method is identical to the one above, except that multiple instances are joined by OR:

```
$this->db->like('title', 'match'); $this->db->or_like('body', $match);
// WHERE `title` LIKE '%match%' ESCAPE '!' OR `body` LIKE '%match%' ESCAPE '!'
```

: `or_like()` was formerly known as `orlike()`, which has been removed.

`$this->db->not_like()`

This method is identical to `like()`, except that it generates NOT LIKE statements:

```
$this->db->not_like('title', 'match'); // WHERE `title` NOT LIKE '%match%' ESCAPE '!'
```

`$this->db->or_not_like()`

This method is identical to `not_like()`, except that multiple instances are joined by OR:

```
$this->db->like('title', 'match');
$this->db->or_not_like('body', 'match');
// WHERE `title` LIKE '%match%' OR `body` NOT LIKE '%match%' ESCAPE '!'
```

`$this->db->group_by()`

Permits you to write the GROUP BY portion of your query:

```
$this->db->group_by("title"); // Produces: GROUP BY title
```

You can also pass an array of multiple values as well:

```
$this->db->group_by(array("title", "date")); // Produces: GROUP BY title, date
```

: `group_by()` was formerly known as `groupby()`, which has been removed.

`$this->db->distinct()`

Adds the “DISTINCT” keyword to a query

```
$this->db->distinct();
$this->db->get('table'); // Produces: SELECT DISTINCT * FROM table
```

`$this->db->having()`

Permits you to write the HAVING portion of your query. There are 2 possible syntaxes, 1 argument or 2:

```
$this->db->having('user_id = 45'); // Produces: HAVING user_id = 45
$this->db->having('user_id', 45); // Produces: HAVING user_id = 45
```

You can also pass an array of multiple values as well:

```
$this->db->having(array('title' => 'My Title', 'id' => $id));  
// Produces: HAVING title = 'My Title', id < 45
```

If you are using a database that CodeIgniter escapes queries for, you can prevent escaping content by passing an optional third argument, and setting it to **FALSE**.

```
$this->db->having('user_id', 45); // Produces: HAVING `user_id` = 45 in some databases such as MySQL  
$this->db->having('user_id', 45, FALSE); // Produces: HAVING user_id = 45
```

`$this->db->or_having()`

Identical to `having()`, only separates multiple clauses with “OR”.

`$this->db->order_by()`

Lets you set an ORDER BY clause.

The first parameter contains the name of the column you would like to order by.

The second parameter lets you set the direction of the result. Options are **ASC**, **DESC** AND **RANDOM**.

```
$this->db->order_by('title', 'DESC');  
// Produces: ORDER BY `title` DESC
```

You can also pass your own string in the first parameter:

```
$this->db->order_by('title DESC, name ASC');  
// Produces: ORDER BY `title` DESC, `name` ASC
```

Or multiple function calls can be made if you need multiple fields.

```
$this->db->order_by('title', 'DESC');  
$this->db->order_by('name', 'ASC');  
// Produces: ORDER BY `title` DESC, `name` ASC
```

If you choose the **RANDOM** direction option, then the first parameters will be ignored, unless you specify a numeric seed value.

```
$this->db->order_by('title', 'RANDOM');  
// Produces: ORDER BY RAND()
```

```
$this->db->order_by(42, 'RANDOM');  
// Produces: ORDER BY RAND(42)
```

: `order_by()` was formerly known as `orderby()`, which has been removed.

: Random ordering is not currently supported in Oracle and will default to ASC instead.

`$this->db->limit()`

Lets you limit the number of rows you would like returned by the query:

```
$this->db->limit(10); // Produces: LIMIT 10
```

The second parameter lets you set a result offset.

```
$this->db->limit(10, 20); // Produces: LIMIT 20, 10 (in MySQL. Other databases have slightly different syntax)
```

`$this->db->count_all_results()`

Permits you to determine the number of rows in a particular Active Record query. Queries will accept Query Builder restrictors such as `where()`, `or_where()`, `like()`, `or_like()`, etc. Example:

```
echo $this->db->count_all_results('my_table'); // Produces an integer, like 25
$this->db->like('title', 'match');
$this->db->from('my_table');
echo $this->db->count_all_results(); // Produces an integer, like 17
```

`$this->db->count_all()`

Permits you to determine the number of rows in a particular table. Submit the table name in the first parameter. Example:

```
echo $this->db->count_all('my_table'); // Produces an integer, like 25
```

Query grouping

Query grouping allows you to create groups of WHERE clauses by enclosing them in parentheses. This will allow you to create queries with complex WHERE clauses. Nested groups are supported. Example:

```
$this->db->select('*')->from('my_table')
    ->group_start()
        ->where('a', 'a')
        ->or_group_start()
            ->where('b', 'b')
            ->where('c', 'c')
        ->group_end()
    ->group_end()
    ->where('d', 'd')
->get();

// Generates:
// SELECT * FROM ('my_table') WHERE ( 'a' = 'a' OR ( 'b' = 'b' AND 'c' = 'c' ) ) AND 'd' = 'd'
```

: groups need to be balanced, make sure every `group_start()` is matched by a `group_end()`.

`$this->db->group_start()`

Starts a new group by adding an opening parenthesis to the WHERE clause of the query.

`$this->db->or_group_start()`

Starts a new group by adding an opening parenthesis to the WHERE clause of the query, prefixing it with 'OR'.

`$this->db->not_group_start()`

Starts a new group by adding an opening parenthesis to the WHERE clause of the query, prefixing it with 'NOT'.

`$this->db->or_not_group_start()`

Starts a new group by adding an opening parenthesis to the WHERE clause of the query, prefixing it with 'OR NOT'.

`$this->db->group_end()`

Ends the current group by adding a closing parenthesis to the WHERE clause of the query.

Inserting Data**`$this->db->insert()`**

Generates an insert string based on the data you supply, and runs the query. You can either pass an **array** or an **object** to the function. Here is an example using an array:

```
$data = array(
    'title' => 'My title',
    'name'  => 'My Name',
    'date'  => 'My date'
);

$this->db->insert('mytable', $data);
// Produces: INSERT INTO mytable (title, name, date) VALUES ('My title', 'My name', 'My date')
```

The first parameter will contain the table name, the second is an associative array of values.

Here is an example using an object:

```
/*
class Myclass {
    public $title = 'My Title';
    public $content = 'My Content';
    public $date = 'My Date';
}
*/

$object = new Myclass;
$this->db->insert('mytable', $object);
// Produces: INSERT INTO mytable (title, content, date) VALUES ('My Title', 'My Content', 'My Date')
```

The first parameter will contain the table name, the second is an object.

: All values are escaped automatically producing safer queries.

`$this->db->get_compiled_insert()`

Compiles the insertion query just like `$this->db->insert()` but does not *run* the query. This method simply returns the SQL query as a string.

Example:

```
$data = array(
    'title' => 'My title',
    'name'  => 'My Name',
    'date'  => 'My date'
);

$sql = $this->db->set($data)->get_compiled_insert('mytable');
echo $sql;

// Produces string: INSERT INTO mytable (title, name, date) VALUES ('My title', 'My name', 'My date')
```

The second parameter enables you to set whether or not the query builder query will be reset (by default it will be—just like `$this->db->insert()`):

```
echo $this->db->set('title', 'My Title')->get_compiled_insert('mytable', FALSE);

// Produces string: INSERT INTO mytable (title) VALUES ('My Title')

echo $this->db->set('content', 'My Content')->get_compiled_insert();

// Produces string: INSERT INTO mytable (title, content) VALUES ('My Title', 'My Content')
```

The key thing to notice in the above example is that the second query did not utilize `$this->db->from()` nor did it pass a table name into the first parameter. The reason this worked is because the query has not been executed using `$this->db->insert()` which resets values or reset directly using `$this->db->reset_query()`.

`$this->db->insert_batch()`

Generates an insert string based on the data you supply, and runs the query. You can either pass an **array** or an **object** to the function. Here is an example using an array:

```
$data = array(
    array(
        'title' => 'My title',
        'name'  => 'My Name',
        'date'  => 'My date'
    ),
    array(
        'title' => 'Another title',
        'name'  => 'Another Name',
        'date'  => 'Another date'
    )
);

$this->db->insert_batch('mytable', $data);
// Produces: INSERT INTO mytable (title, name, date) VALUES ('My title', 'My name', 'My date'), ('Another title', 'Another name', 'Another date')
```

The first parameter will contain the table name, the second is an associative array of values.

: All values are escaped automatically producing safer queries.

`$this->db->replace()`

This method executes a REPLACE statement, which is basically the SQL standard for (optional) DELETE + INSERT, using *PRIMARY* and *UNIQUE* keys as the determining factor. In our case, it will save you from the need to implement complex logics with different combinations of `select()`, `update()`, `delete()` and `insert()` calls.

Example:

```
$data = array(
    'title' => 'My title',
    'name'  => 'My Name',
    'date'  => 'My date'
);

$this->db->replace('table', $data);

// Executes: REPLACE INTO mytable (title, name, date) VALUES ('My title', 'My name', 'My date')
```

In the above example, if we assume that the *title* field is our primary key, then if a row containing 'My title' as the *title* value, that row will be deleted with our new row data replacing it.

Usage of the `set()` method is also allowed and all fields are automatically escaped, just like with `insert()`.

`$this->db->set()`

This function enables you to set values for inserts or updates.

It can be used instead of passing a data array directly to the insert or update functions:

```
$this->db->set('name', $name);
$this->db->insert('mytable'); // Produces: INSERT INTO mytable (name) VALUES ('{$name}')
```

If you use multiple function called they will be assembled properly based on whether you are doing an insert or an update:

```
$this->db->set('name', $name);
$this->db->set('title', $title);
$this->db->set('status', $status);
$this->db->insert('mytable');
```

set() will also accept an optional third parameter (`$escape`), that will prevent data from being escaped if set to `FALSE`. To illustrate the difference, here is `set()` used both with and without the escape parameter.

```
$this->db->set('field', 'field+1', FALSE);
$this->db->insert('mytable'); // gives INSERT INTO mytable (field) VALUES (field+1)
$this->db->set('field', 'field+1');
$this->db->insert('mytable'); // gives INSERT INTO mytable (field) VALUES ('field+1')
```

You can also pass an associative array to this function:

```
$array = array(
    'name' => $name,
    'title' => $title,
    'status' => $status
);

$this->db->set($array);
$this->db->insert('mytable');
```

Or an object:

```
/*
class MyClass {
    public $title = 'My Title';
    public $content = 'My Content';
    public $date = 'My Date';
}
*/

$object = new MyClass;
$this->db->set($object);
$this->db->insert('mytable');
```

Updating Data

`$this->db->update()`

Generates an update string and runs the query based on the data you supply. You can pass an **array** or an **object** to the function. Here is an example using an array:

```
$data = array(
    'title' => $title,
    'name' => $name,
    'date' => $date
);

$this->db->where('id', $id);
$this->db->update('mytable', $data);
// Produces: // UPDATE mytable // SET title = '{$title}', name = '{$name}', date = '{$date}' // WHERE
```

Or you can supply an object:

```
/*
class MyClass {
    public $title = 'My Title';
    public $content = 'My Content';
    public $date = 'My Date';
}
*/

$object = new MyClass;
$this->db->where('id', $id);
$this->db->update('mytable', $object);
// Produces: // UPDATE mytable // SET title = '{$title}', name = '{$name}', date = '{$date}' // WHERE
```

: All values are escaped automatically producing safer queries.

You'll notice the use of the `$this->db->where()` function, enabling you to set the WHERE clause. You can optionally pass this information directly into the update function as a string:

```
$this->db->update('mytable', $data, "id = 4");
```

Or as an array:

```
$this->db->update('mytable', $data, array('id' => $id));
```

You may also use the `$this->db->set()` function described above when performing updates.

`$this->db->update_batch()`

Generates an update string based on the data you supply, and runs the query. You can either pass an **array** or an **object** to the function. Here is an example using an array:

```
$data = array(
    array(
        'title' => 'My title' ,
        'name'  => 'My Name 2' ,
        'date'  => 'My date 2'
    ),
    array(
        'title' => 'Another title' ,
        'name'  => 'Another Name 2' ,
        'date'  => 'Another date 2'
    )
);

$this->db->update_batch('mytable', $data, 'title');

// Produces:
// UPDATE `mytable` SET `name` = CASE
// WHEN `title` = 'My title' THEN 'My Name 2'
// WHEN `title` = 'Another title' THEN 'Another Name 2'
// ELSE `name` END,
// `date` = CASE
// WHEN `title` = 'My title' THEN 'My date 2'
// WHEN `title` = 'Another title' THEN 'Another date 2'
// ELSE `date` END
// WHERE `title` IN ('My title','Another title')
```

The first parameter will contain the table name, the second is an associative array of values, the third parameter is the where key.

: All values are escaped automatically producing safer queries.

: `affected_rows()` won't give you proper results with this method, due to the very nature of how it works. Instead, `update_batch()` returns the number of rows affected.

`$this->db->get_compiled_update()`

This works exactly the same way as `$this->db->get_compiled_insert()` except that it produces an UPDATE SQL string instead of an INSERT SQL string.

For more information view documentation for `$this->db->get_compiled_insert()`.

Deleting Data

`$this->db->delete()`

Generates a delete SQL string and runs the query.

```
$this->db->delete('mytable', array('id' => $id)); // Produces: // DELETE FROM mytable // WHERE id =
```

The first parameter is the table name, the second is the where clause. You can also use the `where()` or `or_where()` functions instead of passing the data to the second parameter of the function:

```
$this->db->where('id', $id);
$this->db->delete('mytable');

// Produces:
// DELETE FROM mytable
// WHERE id = $id
```

An array of table names can be passed into `delete()` if you would like to delete data from more than 1 table.

```
$tables = array('table1', 'table2', 'table3');
$this->db->where('id', '5');
$this->db->delete($tables);
```

If you want to delete all data from a table, you can use the `truncate()` function, or `empty_table()`.

`$this->db->empty_table()`

Generates a delete SQL string and runs the query.:

```
$this->db->empty_table('mytable'); // Produces: DELETE FROM mytable
```

`$this->db->truncate()`

Generates a truncate SQL string and runs the query.

```
$this->db->from('mytable');
$this->db->truncate();

// or

$this->db->truncate('mytable');

// Produce:
// TRUNCATE mytable
```

: If the TRUNCATE command isn't available, `truncate()` will execute as "DELETE FROM table".

`$this->db->get_compiled_delete()`

This works exactly the same way as `$this->db->get_compiled_insert()` except that it produces a DELETE SQL string instead of an INSERT SQL string.

For more information view documentation for `$this->db->get_compiled_insert()`.

Method Chaining

Method chaining allows you to simplify your syntax by connecting multiple functions. Consider this example:

```
$query = $this->db->select('title')
        ->where('id', $id)
        ->limit(10, 20)
        ->get('mytable');
```

Query Builder Caching

While not “true” caching, Query Builder enables you to save (or “cache”) certain parts of your queries for reuse at a later point in your script’s execution. Normally, when an Query Builder call is completed, all stored information is reset for the next call. With caching, you can prevent this reset, and reuse information easily.

Cached calls are cumulative. If you make 2 cached select() calls, and then 2 uncached select() calls, this will result in 4 select() calls. There are three Caching functions available:

`$this->db->start_cache()`

This function must be called to begin caching. All Query Builder queries of the correct type (see below for supported queries) are stored for later use.

`$this->db->stop_cache()`

This function can be called to stop caching.

`$this->db->flush_cache()`

This function deletes all items from the Query Builder cache.

Here’s a usage example:

```
$this->db->start_cache();
$this->db->select('field1');
$this->db->stop_cache();
$this->db->get('tablename');
//Generates: SELECT `field1` FROM (`tablename`)

$this->db->select('field2');
$this->db->get('tablename');
//Generates: SELECT `field1`, `field2` FROM (`tablename`)

$this->db->flush_cache();
$this->db->select('field2');
$this->db->get('tablename');
//Generates: SELECT `field2` FROM (`tablename`)
```

: The following statements can be cached: select, from, join, where, like, group_by, having, order_by, set

`$this->db->reset_query()`

Resetting Query Builder allows you to start fresh with your query without executing it first using a method like `$this->db->get()` or `$this->db->insert()`. Just like the methods that execute a query, this will *not* reset items you’ve cached using Query Builder Caching.

This is useful in situations where you are using Query Builder to generate SQL (ex. `$this->db->get_compiled_select()`) but then choose to, for instance, run the query:

```
// Note that the second parameter of the get_compiled_select method is FALSE
$sql = $this->db->select(array('field1','field2'))
        ->where('field3',5)
        ->get_compiled_select('mytable', FALSE);

// ...
// Do something crazy with the SQL code... like add it to a cron script for
// later execution or something...
// ...

$data = $this->db->get()->result_array();

// Would execute and return an array of results of the following query:
// SELECT field1, field1 from mytable where field3 = 5;
```

10.15.8 Transactions

CodeIgniter's database abstraction allows you to use transactions with databases that support transaction-safe table types. In MySQL, you'll need to be running InnoDB or BDB table types rather than the more common MyISAM. Most other database platforms support transactions natively.

If you are not familiar with transactions we recommend you find a good online resource to learn about them for your particular database. The information below assumes you have a basic understanding of transactions.

CodeIgniter's Approach to Transactions

CodeIgniter utilizes an approach to transactions that is very similar to the process used by the popular database class ADODB. We've chosen that approach because it greatly simplifies the process of running transactions. In most cases all that is required are two lines of code.

Traditionally, transactions have required a fair amount of work to implement since they demand that you to keep track of your queries and determine whether to commit or rollback based on the success or failure of your queries. This is particularly cumbersome with nested queries. In contrast, we've implemented a smart transaction system that does all this for you automatically (you can also manage your transactions manually if you choose to, but there's really no benefit).

Running Transactions

To run your queries using transactions you will use the `$this->db->trans_start()` and `$this->db->trans_complete()` functions as follows:

```
$this->db->trans_start();
$this->db->query('AN SQL QUERY...');
$this->db->query('ANOTHER QUERY...');
$this->db->query('AND YET ANOTHER QUERY...');
$this->db->trans_complete();
```

You can run as many queries as you want between the start/complete functions and they will all be committed or rolled back based on success or failure of any given query.

Strict Mode

By default CodeIgniter runs all transactions in Strict Mode. When strict mode is enabled, if you are running multiple groups of transactions, if one group fails all groups will be rolled back. If strict mode is disabled, each group is treated independently, meaning a failure of one group will not affect any others.

Strict Mode can be disabled as follows:

```
$this->db->trans_strict(FALSE);
```

Managing Errors

If you have error reporting enabled in your config/database.php file you'll see a standard error message if the commit was unsuccessful. If debugging is turned off, you can manage your own errors like this:

```
$this->db->trans_start();
$this->db->query('AN SQL QUERY...');
$this->db->query('ANOTHER QUERY...');
$this->db->trans_complete();

if ($this->db->trans_status() === FALSE)
{
    // generate an error... or use the log_message() function to log your error
}
```

Enabling Transactions

Transactions are enabled automatically the moment you use `$this->db->trans_start()`. If you would like to disable transactions you can do so using `$this->db->trans_off()`:

```
$this->db->trans_off();

$this->db->trans_start();
$this->db->query('AN SQL QUERY...');
$this->db->trans_complete();
```

When transactions are disabled, your queries will be auto-committed, just as they are when running queries without transactions.

Test Mode

You can optionally put the transaction system into “test mode”, which will cause your queries to be rolled back – even if the queries produce a valid result. To use test mode simply set the first parameter in the `$this->db->trans_start()` function to `TRUE`:

```
$this->db->trans_start(TRUE); // Query will be rolled back
$this->db->query('AN SQL QUERY...');
$this->db->trans_complete();
```

Running Transactions Manually

If you would like to run transactions manually you can do so as follows:

```
$this->db->trans_begin();

$this->db->query('AN SQL QUERY...');
$this->db->query('ANOTHER QUERY...');
$this->db->query('AND YET ANOTHER QUERY...');

if ($this->db->trans_status() === FALSE)
{
    $this->db->trans_rollback();
}
else
{
    $this->db->trans_commit();
}
```

: Make sure to use `$this->db->trans_begin()` when running manual transactions, **NOT** `$this->db->trans_start()`.

10.15.9 Table Data

These functions let you fetch table information.

`$this->db->list_tables();`

Returns an array containing the names of all the tables in the database you are currently connected to. Example:

```
$tables = $this->db->list_tables();

foreach ($tables as $table)
{
    echo $table;
}
```

`$this->db->table_exists();`

Sometimes it's helpful to know whether a particular table exists before running an operation on it. Returns a boolean TRUE/FALSE. Usage example:

```
if ($this->db->table_exists('table_name'))
{
    // some code...
}
```

: Replace *table_name* with the name of the table you are looking for.

10.15.10 Field Data

`$this->db->list_fields()`

Returns an array containing the field names. This query can be called two ways:

1. You can supply the table name and call it from the `$this->db->` object:

```
$fields = $this->db->list_fields('table_name');

foreach ($fields as $field)
{
    echo $field;
}
```

2. You can gather the field names associated with any query you run by calling the function from your query result object:

```
$query = $this->db->query('SELECT * FROM some_table');

foreach ($query->list_fields() as $field)
{
    echo $field;
}
```

`$this->db->field_exists()`

Sometimes it's helpful to know whether a particular field exists before performing an action. Returns a boolean TRUE/FALSE. Usage example:

```
if ($this->db->field_exists('field_name', 'table_name'))
{
    // some code...
}
```

: Replace *field_name* with the name of the column you are looking for, and replace *table_name* with the name of the table you are looking for.

`$this->db->field_data()`

Returns an array of objects containing field information.

Sometimes it's helpful to gather the field names or other metadata, like the column type, max length, etc.

: Not all databases provide meta-data.

Usage example:

```
$fields = $this->db->field_data('table_name');

foreach ($fields as $field)
{
    echo $field->name;
    echo $field->type;
    echo $field->max_length;
    echo $field->primary_key;
}
```

If you have run a query already you can use the result object instead of supplying the table name:

```
$query = $this->db->query("YOUR QUERY");
$fields = $query->field_data();
```

The following data is available from this function if supported by your database:

- name - column name
- max_length - maximum length of the column
- primary_key - 1 if the column is a primary key
- type - the type of the column

10.15.11 Custom Function Calls

`$this->db->call_function();`

This function enables you to call PHP database functions that are not natively included in CodeIgniter, in a platform independent manner. For example, let's say you want to call the `mysql_get_client_info()` function, which is **not** natively supported by CodeIgniter. You could do so like this:

```
$this->db->call_function('get_client_info');
```

You must supply the name of the function, **without** the `mysql_` prefix, in the first parameter. The prefix is added automatically based on which database driver is currently being used. This permits you to run the same function on different database platforms. Obviously not all function calls are identical between platforms, so there are limits to how useful this function can be in terms of portability.

Any parameters needed by the function you are calling will be added to the second parameter.

```
$this->db->call_function('some_function', $param1, $param2, etc.);
```

Often, you will either need to supply a database connection ID or a database result ID. The connection ID can be accessed using:

```
$this->db->conn_id;
```

The result ID can be accessed from within your result object, like this:

```
$query = $this->db->query("SOME QUERY");
```

```
$query->result_id;
```

10.15.12 Database Caching Class

The Database Caching Class permits you to cache your queries as text files for reduced database load.

: This class is initialized automatically by the database driver when caching is enabled. Do NOT load this class manually.

: Not all query result functions are available when you use caching. Please read this page carefully.

Enabling Caching

Caching is enabled in three steps:

- Create a writable directory on your server where the cache files can be stored.
- Set the path to your cache folder in your application/config/database.php file.

- Enable the caching feature, either globally by setting the preference in your application/config/database.php file, or manually as described below.

Once enabled, caching will happen automatically whenever a page is loaded that contains database queries.

How Does Caching Work?

CodeIgniter's query caching system happens dynamically when your pages are viewed. When caching is enabled, the first time a web page is loaded, the query result object will be serialized and stored in a text file on your server. The next time the page is loaded the cache file will be used instead of accessing your database. Your database usage can effectively be reduced to zero for any pages that have been cached.

Only read-type (SELECT) queries can be cached, since these are the only type of queries that produce a result. Write-type (INSERT, UPDATE, etc.) queries, since they don't generate a result, will not be cached by the system.

Cache files DO NOT expire. Any queries that have been cached will remain cached until you delete them. The caching system permits you clear caches associated with individual pages, or you can delete the entire collection of cache files. Typically you'll want to use the housekeeping functions described below to delete cache files after certain events take place, like when you've added new information to your database.

Will Caching Improve Your Site's Performance?

Getting a performance gain as a result of caching depends on many factors. If you have a highly optimized database under very little load, you probably won't see a performance boost. If your database is under heavy use you probably will see an improved response, assuming your file-system is not overly taxed. Remember that caching simply changes how your information is retrieved, shifting it from being a database operation to a file-system one.

In some clustered server environments, for example, caching may be detrimental since file-system operations are so intense. On single servers in shared environments, caching will probably be beneficial. Unfortunately there is no single answer to the question of whether you should cache your database. It really depends on your situation.

How are Cache Files Stored?

CodeIgniter places the result of EACH query into its own cache file. Sets of cache files are further organized into sub-folders corresponding to your controller functions. To be precise, the sub-folders are named identically to the first two segments of your URI (the controller class name and function name).

For example, let's say you have a controller called blog with a function called comments that contains three queries. The caching system will create a cache folder called blog+comments, into which it will write three cache files.

If you use dynamic queries that change based on information in your URI (when using pagination, for example), each instance of the query will produce its own cache file. It's possible, therefore, to end up with many times more cache files than you have queries.

Managing your Cache Files

Since cache files do not expire, you'll need to build deletion routines into your application. For example, let's say you have a blog that allows user commenting. Whenever a new comment is submitted you'll want to delete the cache files associated with the controller function that serves up your comments. You'll find two delete functions described below that help you clear data.

Not All Database Functions Work with Caching

Lastly, we need to point out that the result object that is cached is a simplified version of the full result object. For that reason, some of the query result functions are not available for use.

The following functions ARE NOT available when using a cached result object:

- `num_fields()`
- `field_names()`
- `field_data()`
- `free_result()`

Also, the two database resources (`result_id` and `conn_id`) are not available when caching, since result resources only pertain to run-time operations.

Function Reference

`$this->db->cache_on()` / `$this->db->cache_off()`

Manually enables/disables caching. This can be useful if you want to keep certain queries from being cached. Example:

```
// Turn caching on
$this->db->cache_on();
$query = $this->db->query("SELECT * FROM mytable");

// Turn caching off for this one query
$this->db->cache_off();
$query = $this->db->query("SELECT * FROM members WHERE member_id = '$current_user'");

// Turn caching back on
$this->db->cache_on();
$query = $this->db->query("SELECT * FROM another_table");
```

`$this->db->cache_delete()`

Deletes the cache files associated with a particular page. This is useful if you need to clear caching after you update your database.

The caching system saves your cache files to folders that correspond to the URI of the page you are viewing. For example, if you are viewing a page at `example.com/index.php/blog/comments`, the caching system will put all cache files associated with it in a folder called `blog+comments`. To delete those particular cache files you will use:

```
$this->db->cache_delete('blog', 'comments');
```

If you do not use any parameters the current URI will be used when determining what should be cleared.

`$this->db->cache_delete_all()`

Clears all existing cache files. Example:

```
$this->db->cache_delete_all();
```

10.15.13 Database Forge Class

The Database Forge Class contains methods that help you manage your database.

Table of Contents

- Database Forge Class
 - Initializing the Forge Class
 - * `$this->dbforge->create_database('db_name')`
 - * `$this->dbforge->drop_database('db_name')`
 - Creating and Dropping Tables
 - * Adding fields
 - `$this->dbforge->add_field()`
 - Passing strings as fields
 - Creating an id field
 - * Adding Keys
 - * Creating a table
 - * Dropping a table
 - * Renaming a table
 - Modifying Tables
 - * `$this->dbforge->add_column()`
 - * `$this->dbforge->drop_column()`
 - * `$this->dbforge->modify_column()`

Initializing the Forge Class

: In order to initialize the Forge class, your database driver must already be running, since the forge class relies on it.

Load the Forge Class as follows:

```
$this->load->dbforge();
```

You can also pass another database object to the DB Forge loader, in case the database you want to manage isn't the default one:

```
$this->myforge = $this->load->dbforge($this->other_db, TRUE);
```

In the above example, we're passing a custom database object as the first parameter and then tell it to return the dbforge object, instead of assigning it directly to `$this->dbforge`.

: Both of the parameters can be used individually, just pass an empty value as the first one if you wish to skip it.

Once initialized you will access the methods using the `$this->dbforge` object:

```
$this->dbforge->some_method();
```

`$this->dbforge->create_database('db_name')`

Permits you to create the database specified in the first parameter. Returns TRUE/FALSE based on success or failure:

```
if ($this->dbforge->create_database('my_db'))
{
    echo 'Database created!';
}
```

`$this->dbforge->drop_database('db_name')`

Permits you to drop the database specified in the first parameter. Returns TRUE/FALSE based on success or failure:

```
if ($this->dbforge->drop_database('my_db'))
{
    echo 'Database deleted!';
}
```

Creating and Dropping Tables

There are several things you may wish to do when creating tables. Add fields, add keys to the table, alter columns. CodeIgniter provides a mechanism for this.

Adding fields

Fields are created via an associative array. Within the array you must include a 'type' key that relates to the datatype of the field. For example, INT, VARCHAR, TEXT, etc. Many datatypes (for example VARCHAR) also require a 'constraint' key.

```
$fields = array(
    'users' => array(
        'type' => 'VARCHAR',
        'constraint' => '100',
    ),
);
// will translate to "users VARCHAR(100)" when the field is added.
```

Additionally, the following key/values can be used:

- `unsigned/true` : to generate “UNSIGNED” in the field definition.
- `default/value` : to generate a default value in the field definition.
- `null/true` : to generate “NULL” in the field definition. Without this, the field will default to “NOT NULL”.
- `auto_increment/true` : generates an `auto_increment` flag on the field. Note that the field type must be a type that supports this, such as integer.

```
$fields = array(
    'blog_id' => array(
        'type' => 'INT',
        'constraint' => 5,
        'unsigned' => TRUE,
        'auto_increment' => TRUE
    ),
    'blog_title' => array(
        'type' => 'VARCHAR',
        'constraint' => '100',
    ),
    'blog_author' => array(
```

```
        'type' => 'VARCHAR',
        'constraint' => '100',
        'default' => 'King of Town',
    ),
    'blog_description' => array(
        'type' => 'TEXT',
        'null' => TRUE,
    ),
);
```

After the fields have been defined, they can be added using `$this->dbforge->add_field($fields);` followed by a call to the `create_table()` method.

`$this->dbforge->add_field()` The add fields method will accept the above array.

Passing strings as fields If you know exactly how you want a field to be created, you can pass the string into the field definitions with `add_field()`

```
$this->dbforge->add_field("label varchar(100) NOT NULL DEFAULT 'default label'");
```

: Multiple calls to `add_field()` are cumulative.

Creating an id field There is a special exception for creating id fields. A field with type `id` will automatically be assigned as an `INT(9)` `auto_incrementing` Primary Key.

```
$this->dbforge->add_field('id');
// gives id INT(9) NOT NULL AUTO_INCREMENT
```

Adding Keys

Generally speaking, you'll want your table to have Keys. This is accomplished with `$this->dbforge->add_key('field')`. An optional second parameter set to `TRUE` will make it a primary key. Note that `add_key()` must be followed by a call to `create_table()`.

Multiple column non-primary keys must be sent as an array. Sample output below is for MySQL.

```
$this->dbforge->add_key('blog_id', TRUE);
// gives PRIMARY KEY `blog_id` (`blog_id`)

$this->dbforge->add_key('blog_id', TRUE);
$this->dbforge->add_key('site_id', TRUE);
// gives PRIMARY KEY `blog_id_site_id` (`blog_id`, `site_id`)

$this->dbforge->add_key('blog_name');
// gives KEY `blog_name` (`blog_name`)

$this->dbforge->add_key(array('blog_name', 'blog_label'));
// gives KEY `blog_name_blog_label` (`blog_name`, `blog_label`)
```

Creating a table

After fields and keys have been declared, you can create a new table with

```
$this->dbforge->create_table('table_name');
// gives CREATE TABLE table_name
```

An optional second parameter set to TRUE adds an “IF NOT EXISTS” clause into the definition

```
$this->dbforge->create_table('table_name', TRUE);
// gives CREATE TABLE IF NOT EXISTS table_name
```

Dropping a table

Execute a DROP TABLE statement and optionally add an IF EXISTS clause.

```
// Produces: DROP TABLE table_name
$this->dbforge->drop_table('table_name');

// Produces: DROP TABLE IF EXISTS table_name
$this->dbforge->drop_table('table_name');
```

Renaming a table

Executes a TABLE rename

```
$this->dbforge->rename_table('old_table_name', 'new_table_name');
// gives ALTER TABLE old_table_name RENAME TO new_table_name
```

Modifying Tables

`$this->dbforge->add_column()`

The `add_column()` method is used to modify an existing table. It accepts the same field array as above, and can be used for an unlimited number of additional fields.

```
$fields = array(
    'preferences' => array('type' => 'TEXT')
);
$this->dbforge->add_column('table_name', $fields);
// Executes: ALTER TABLE table_name ADD preferences TEXT
```

If you are using MySQL or CUBIRD, then you can take advantage of their AFTER and FIRST clauses to position the new column.

Examples:

```
// Will place the new column after the 'another_field' column:
$fields = array(
    'preferences' => array('type' => 'TEXT', 'after' => 'another_field')
);

// Will place the new column at the start of the table definition:
$fields = array(
    'preferences' => array('type' => 'TEXT', 'first' => TRUE)
);
```

`$this->dbforge->drop_column()`

Used to remove a column from a table.

```
$this->dbforge->drop_column('table_name', 'column_to_drop');
```

`$this->dbforge->modify_column()`

The usage of this method is identical to `add_column()`, except it alters an existing column rather than adding a new one. In order to change the name you can add a “name” key into the field defining array.

```
$fields = array(
    'old_name' => array(
        'name' => 'new_name',
        'type' => 'TEXT',
    ),
);
$this->dbforge->modify_column('table_name', $fields);
// gives ALTER TABLE table_name CHANGE old_name new_name TEXT
```

10.15.14 Database Utility Class

The Database Utility Class contains methods that help you manage your database.

Table of Contents

- Database Utility Class
 - Function Reference
 - * Initializing the Utility Class
 - * `$this->dbutil->list_databases();`
 - * `$this->dbutil->database_exists();`
 - * `$this->dbutil->optimize_table('table_name');`
 - * `$this->dbutil->repair_table('table_name');`
 - * `$this->dbutil->optimize_database();`
 - * `$this->dbutil->csv_from_result($db_result);`
 - * `$this->dbutil->xml_from_result($db_result);`
 - * `$this->dbutil->backup();`
 - Usage Example
 - Setting Backup Preferences
 - Description of Backup Preferences

Function Reference

Initializing the Utility Class

: In order to initialize the Utility class, your database driver must already be running, since the utilities class relies on it.

Load the Utility Class as follows:

```
$this->load->dbutil();
```

You can also pass another database object to the DB Utility loader, in case the database you want to manage isn't the default one:

```
$this->myutil = $this->load->dbutil($this->other_db, TRUE);
```

In the above example, we're passing a custom database object as the first parameter and then tell it to return the dbutil object, instead of assigning it directly to `$this->dbutil`.

: Both of the parameters can be used individually, just pass an empty value as the first one if you wish to skip it.

Once initialized you will access the methods using the `$this->dbutil` object:

```
$this->dbutil->some_method();
```

`$this->dbutil->list_databases();`

Returns an array of database names:

```
$dbs = $this->dbutil->list_databases();

foreach ($dbs as $db)
{
    echo $db;
}
```

`$this->dbutil->database_exists();`

Sometimes it's helpful to know whether a particular database exists. Returns a boolean TRUE/FALSE. Usage example:

```
if ($this->dbutil->database_exists('database_name'))
{
    // some code...
}
```

: Replace *database_name* with the name of the table you are looking for. This method is case sensitive.

`$this->dbutil->optimize_table('table_name');`

Permits you to optimize a table using the table name specified in the first parameter. Returns TRUE/FALSE based on success or failure:

```
if ($this->dbutil->optimize_table('table_name'))
{
    echo 'Success!';
}
```

: Not all database platforms support table optimization. It is mostly for use with MySQL.

`$this->dbutil->repair_table('table_name');`

Permits you to repair a table using the table name specified in the first parameter. Returns TRUE/FALSE based on success or failure:

```
if ($this->dbutil->repair_table('table_name'))
{
    echo 'Success!';
}
```

: Not all database platforms support table repairs.

`$this->dbutil->optimize_database();`

Permits you to optimize the database your DB class is currently connected to. Returns an array containing the DB status messages or FALSE on failure.

```
$result = $this->dbutil->optimize_database();

if ($result !== FALSE)
{
    print_r($result);
}
```

: Not all database platforms support table optimization. It is mostly for use with MySQL.

`$this->dbutil->csv_from_result($db_result);`

Permits you to generate a CSV file from a query result. The first parameter of the method must contain the result object from your query. Example:

```
$this->load->dbutil();

$query = $this->db->query("SELECT * FROM mytable");

echo $this->dbutil->csv_from_result($query);
```

The second, third, and fourth parameters allow you to set the delimiter newline, and enclosure characters respectively. By default commas are used as the delimiter, “n” is used as a new line, and a double-quote is used as the enclosure. Example:

```
$delimiter = ",";
$newline = "\r\n";
$enclosure = '"';

echo $this->dbutil->csv_from_result($query, $delimiter, $newline, $enclosure);
```

: This method will NOT write the CSV file for you. It simply creates the CSV layout. If you need to write the file use the *File Helper*.

```
$this->dbutil->xml_from_result($db_result);
```

Permits you to generate an XML file from a query result. The first parameter expects a query result object, the second may contain an optional array of config parameters. Example:

```
$this->load->dbutil();

$query = $this->db->query("SELECT * FROM mytable");

$config = array (
    'root'          => 'root',
    'element'       => 'element',
    'newline'       => "\n",
    'tab'           => "\t"
);

echo $this->dbutil->xml_from_result($query, $config);
```

: This method will NOT write the XML file for you. It simply creates the XML layout. If you need to write the file use the *File Helper*.

```
$this->dbutil->backup();
```

Permits you to backup your full database or individual tables. The backup data can be compressed in either Zip or Gzip format.

: This feature is only available for MySQL and Interbase/Firebird databases.

: For Interbase/Firebird databases, the backup file name is the only parameter.

Eg. `$this->dbutil->backup('db_backup_filename');`

: Due to the limited execution time and memory available to PHP, backing up very large databases may not be possible. If your database is very large you might need to backup directly from your SQL server via the command line, or have your server admin do it for you if you do not have root privileges.

Usage Example

```
// Load the DB utility class
$this->load->dbutil();

// Backup your entire database and assign it to a variable
$backup =& $this->dbutil->backup();

// Load the file helper and write the file to your server
$this->load->helper('file');
write_file('/path/to/mybackup.gz', $backup);

// Load the download helper and send the file to your desktop
$this->load->helper('download');
force_download('mybackup.gz', $backup);
```

Setting Backup Preferences Backup preferences are set by submitting an array of values to the first parameter of the `backup()` method. Example:

```
$prefs = array(
    'tables'      => array('table1', 'table2'), // Array of tables to backup.
    'ignore'      => array(),                 // List of tables to omit from the backup
    'format'      => 'txt',                   // gzip, zip, txt
    'filename'    => 'mybackup.sql',          // File name - NEEDED ONLY WITH ZIP FILES
    'add_drop'    => TRUE,                   // Whether to add DROP TABLE statements to backup file
    'add_insert'  => TRUE,                   // Whether to add INSERT data to backup file
    'newline'     => "\n"                    // Newline character used in backup file
);

$this->dbutil->backup($prefs);
```

Description of Backup Preferences

Preference	Default Value	Options	Description
tables	empty array	None	An array of tables you want backed up. If left empty, all tables will be exported.
ignore	empty array	None	An array of tables you want the backup routine to ignore.
format	gzip	gzip, zip, txt	The file format of the export file.
filename	the current date/time	None	The name of the backed-up file. The name is automatically generated if you are using zip compression.
add_drop	TRUE	TRUE/FALSE	Whether to include DROP TABLE statements in the backup export file.
add_insert	TRUE	TRUE/FALSE	Whether to include INSERT statements in your backup.
newline	"\n"	"\n", "\r", "\r\n"	Type of newline to use in your SQL export file.
foreign_key_checks	TRUE	TRUE/FALSE	Whether output should keep foreign key checks disabled.

10.16 Writing CodeIgniter Documentation

CodeIgniter uses Sphinx to generate its documentation in a variety of formats, using reStructuredText to handle the formatting. If you are familiar with Markdown or Textile, you will quickly grasp reStructuredText. The focus is on readability, user friendliness, and an “I’ve got your hand, baby” feel. While they can be quite technical, we always write for humans!

A table of contents should always be included like the one below. It is created automatically by inserting the `.. contents::` directive on a line by itself.

Page Contents

- Writing CodeIgniter Documentation
 - Tools Required
 - Page and Section Headings and Subheadings
 - Method Documentation
 - * `some_method()`
 - * `should_do_something()`

10.16.1 Tools Required

To see the rendered HTML, ePub, PDF, etc., you will need to install Sphinx along with the PHP domain extension for Sphinx. The underlying requirement is to have Python installed. Lastly, you will install the CI Lexer for Pygments, so that code blocks can be properly highlighted.

```
easy_install sphinx
easy_install sphinxcontrib-phpdomain
```

Then follow the directions in the README file in the `cilexer` folder inside the documentation repository to install the CI Lexer.

10.16.2 Page and Section Headings and Subheadings

Headings not only provide order and sections within a page, but they also are used to automatically build both the page and document table of contents. Headings are formed by using certain characters as underlines for a bit of text. Major headings, like page titles and section headings also use overlines. Other headings just use underlines, with the following hierarchy:

```
# with overline for page titles
* with overline for major sections
= for subsections
- for subsubsections
^ for subsubsubsections
" for subsubsubsubsections (!)
```

The TextMate ELDocs Bundle can help you create these with the following tab triggers:

title->

```
#####
Page Title
#####
```

sec->

```
*****
Major Section
*****
```

sub->

```
Subsection
=====
```

sss->

```
SubSubSection
-----
```

ssss->

```
SubSubSubSection
^^^^^^^^^^^^^^^^
```

sssss->

```
SubSubSubSubSection (!)
!!!!!!!!!!!!!!!!!!!!!!!!!!!!
```

10.16.3 Method Documentation

When documenting class methods for third party developers, Sphinx provides directives to assist and keep things simple. For example, consider the following ReST:

```
.. php:class:: Some_class

some_method()
=====

.. php:method:: some_method ( $foo [, $bar [, $bat]])

    This function will perform some action. The ``$bar`` array must contain
    a something and something else, and along with ``$bat`` is an optional
    parameter.

    :param int $foo: the foo id to do something in
    :param mixed $bar: A data array that must contain aa something and something else
    :param bool $bat: whether or not to do something
    :returns: FALSE on failure, TRUE if successful
    :rtype: Boolean

    ::

        $this->load->library('some_class');

        $bar = array(
            'something'           => 'Here is this parameter!',
            'something_else'      => 42
        );

        $bat = $this->some_class->should_do_something();

        if ($this->some_class->some_method(4, $bar, $bat) === FALSE)
        {
            show_error('An Error Occurred Doing Some Method');
        }

.. note:: Here is something that you should be aware of when using some_method().
        For real.

    See also :php:meth:`Some_class::should_do_something`

should_do_something()
=====

.. php:method:: should_do_something()

    :returns: whether or something should be done or not
    :rtype: Boolean
```

It creates the following display:

```
class Some_class
```

some_method()

`Some_class::some_method($foo[, $bar[, $bat]])`

This function will perform some action. The `$bar` array must contain a something and something else, and along with `$bat` is an optional parameter.

- **\$foo** (*int*) – the foo id to do something in
- **\$bar** (*mixed*) – A data array that must contain aa something and something else
- **\$bat** (*bool*) – whether or not to do something

FALSE on failure, TRUE if successful

Boolean

```

$this->load->library('some_class');

$bar = array(
    'something'           => 'Here is this parameter!',
    'something_else'      => 42
);

$bat = $this->some_class->should_do_something();

if ($this->some_class->some_method(4, $bar, $bat) === FALSE)
{
    show_error('An Error Occurred Doing Some Method');
}

```

: Here is something that you should be aware of when using `some_method()`. For real.

See also `Some_class::should_do_something`

should_do_something()

`Some_class::should_do_something()`

whether or something should be done or not

Boolean

10.17 Tutorial

This tutorial is intended to introduce you to the CodeIgniter framework and the basic principles of MVC architecture. It will show you how a basic CodeIgniter application is constructed in step-by-step fashion.

In this tutorial, you will be creating a **basic news application**. You will begin by writing the code that can load static pages. Next, you will create a news section that reads news items from a database. Finally, you'll add a form to create news items in the database.

This tutorial will primarily focus on:

- Model-View-Controller basics
- Routing basics

- Form validation
- Performing basic database queries using “Query Builder”

The entire tutorial is split up over several pages, each explaining a small part of the functionality of the CodeIgniter framework. You’ll go through the following pages:

- Introduction, this page, which gives you an overview of what to expect.
- Static pages, which will teach you the basics of controllers, views and routing.
- News section, where you’ll start using models and will be doing some basic database operations.
- Create news items, which will introduce more advanced database operations and form validation.
- Conclusion, which will give you some pointers on further reading and other resources.

Enjoy your exploration of the CodeIgniter framework.

10.17.1 Static pages

Note: This tutorial assumes you’ve downloaded CodeIgniter and installed the framework in your development environment.

The first thing you’re going to do is set up a **controller** to handle static pages. A controller is simply a class that helps delegate work. It is the glue of your web application.

For example, when a call is made to: `http://example.com/news/latest/10` We might imagine that there is a controller named “news”. The method being called on news would be “latest”. The news method’s job could be to grab 10 news items, and render them on the page. Very often in MVC, you’ll see URL patterns that match: `http://example.com/[controller-class]/[controller-method]/[arguments]` As URL schemes become more complex, this may change. But for now, this is all we will need to know.

Create a file at `application/controllers/Pages.php` with the following code.

```
<?php
class Pages extends CI_Controller {

    public function view($page = 'home')
    {

    }

}
```

You have created a class named “pages”, with a view method that accepts one argument named \$page. The pages class is extending the CI_Controller class. This means that the new pages class can access the methods and variables defined in the CI_Controller class (`system/core/Controller.php`).

The **controller is what will become the center of every request** to your web application. In very technical CodeIgniter discussions, it may be referred to as the *super object*. Like any php class, you refer to it within your controllers as \$this. Referring to \$this is how you will load libraries, views, and generally command the framework.

Now you’ve created your first method, it’s time to make some basic page templates. We will be creating two “views” (page templates) that act as our page footer and header.

Create the header at `application/views/templates/header.php` and add the following code.

```
<html>
    <head>
        <title>CodeIgniter Tutorial</title>
    </head>
```

```
<body>

    <h1>CodeIgniter Tutorial</h1>
```

The header contains the basic HTML code that you'll want to display before loading the main view, together with a heading. It will also output the \$title variable, which we'll define later in the controller. Now create a footer at application/views/templates/footer.php that includes the following code:

```
    <em>&copy; 2013</em>
</body>
</html>
```

Adding logic to the controller

Earlier you set up a controller with a view() method. The method accepts one parameter, which is the name of the page to be loaded. The static page templates will be located in the application/views/pages/ directory.

In that directory, create two files named home.php and about.php. Within those files, type some text anything you'd like and save them. If you like to be particularly un-original, try "Hello World!".

In order to load those pages, you'll have to check whether the requested page actually exists:

```
<?php
public function view($page = 'home')
{

    if ( ! file_exists(APPPATH.'/views/pages/'.$page.'.php'))
    {
        // Whoops, we don't have a page for that!
        show_404();
    }

    $data['title'] = ucfirst($page); // Capitalize the first letter

    $this->load->view('templates/header', $data);
    $this->load->view('pages/'.$page, $data);
    $this->load->view('templates/footer', $data);

}
```

Now, when the page does exist, it is loaded, including the header and footer, and displayed to the user. If the page doesn't exist, a "404 Page not found" error is shown.

The first line in this method checks whether the page actually exists. PHP's native file_exists() function is used to check whether the file is where it's expected to be. show_404() is a built-in CodeIgniter function that renders the default error page.

In the header template, the \$title variable was used to customize the page title. The value of title is defined in this method, but instead of assigning the value to a variable, it is assigned to the title element in the \$data array.

The last thing that has to be done is loading the views in the order they should be displayed. The second parameter in the view() method is used to pass values to the view. Each value in the \$data array is assigned to a variable with the name of its key. So the value of \$data['title'] in the controller is equivalent to \$title in the view.

Routing

The controller is now functioning! Point your browser to [your-site-url]index.php/pages/view to see your page. When you visit index.php/pages/view/about you'll see the about page, again including the header and footer.

Using custom routing rules, you have the power to map any URI to any controller and method, and break free from the normal convention: `http://example.com/[controller-class]/[controller-method]/[arguments]`

Let's do that. Open the routing file located at `application/config/routes.php` and add the following two lines. Remove all other code that sets any element in the `$route` array.

```
$route['default_controller'] = 'pages/view';
$route['(:any)'] = 'pages/view/$1';
```

CodeIgniter reads its routing rules from top to bottom and routes the request to the first matching rule. Each rule is a regular expression (left-side) mapped to a controller and method name separated by slashes (right-side). When a request comes in, CodeIgniter looks for the first match, and calls the appropriate controller and method, possibly with arguments.

More information about routing can be found in the [URI Routing](#) documentation.

Here, the second rule in the `$routes` array matches **any** request using the wildcard string `(:any)`. and passes the parameter to the `view()` method of the `pages` class.

Now visit `index.php/about`. Did it get routed correctly to the `view()` method in the `pages` controller? Awesome!

10.17.2 News section

In the last section, we went over some basic concepts of the framework by writing a class that includes static pages. We cleaned up the URI by adding custom routing rules. Now it's time to introduce dynamic content and start using a database.

Setting up your model

Instead of writing database operations right in the controller, queries should be placed in a model, so they can easily be reused later. Models are the place where you retrieve, insert, and update information in your database or other data stores. They represent your data.

Open up the `application/models` directory and create a new file called `News_model.php` and add the following code. Make sure you've configured your database properly as described here.

```
<?php
class News_model extends CI_Model {

    public function __construct()
    {
        $this->load->database();
    }

}
```

This code looks similar to the controller code that was used earlier. It creates a new model by extending `CI_Model` and loads the database library. This will make the database class available through the `$this->db` object.

Before querying the database, a database schema has to be created. Connect to your database and run the SQL command below. Also add some seed records.

```
CREATE TABLE news (
    id int(11) NOT NULL AUTO_INCREMENT,
    title varchar(128) NOT NULL,
    slug varchar(128) NOT NULL,
    text text NOT NULL,
    PRIMARY KEY (id),
```

```

        KEY slug (slug)
    );

```

Now that the database and a model have been set up, you'll need a method to get all of our posts from our database. To do this, the database abstraction layer that is included with CodeIgniter — Active Record — is used. This makes it possible to write your 'queries' once and make them work on all supported database systems. Add the following code to your model.

```

public function get_news($slug = FALSE)
{
    if ($slug === FALSE)
    {
        $query = $this->db->get('news');
        return $query->result_array();
    }

    $query = $this->db->get_where('news', array('slug' => $slug));
    return $query->row_array();
}

```

With this code you can perform two different queries. You can get all news records, or get a news item by its slug. You might have noticed that the \$slug variable wasn't sanitized before running the query; *Query Builder* does this for you.

Display the news

Now that the queries are written, the model should be tied to the views that are going to display the news items to the user. This could be done in our pages controller created earlier, but for the sake of clarity, a new "news" controller is defined. Create the new controller at application/controllers/News.php.

```

<?php
class News extends CI_Controller {

    public function __construct()
    {
        parent::__construct();
        $this->load->model('news_model');
    }

    public function index()
    {
        $data['news'] = $this->news_model->get_news();
    }

    public function view($slug = NULL)
    {
        $data['news_item'] = $this->news_model->get_news($slug);
    }
}

```

Looking at the code, you may see some similarity with the files we created earlier. First, the `__construct()` method: it calls the constructor of its parent class (`CI_Controller`) and loads the model, so it can be used in all other methods in this controller.

Next, there are two methods to view all news items and one for a specific news item. You can see that the \$slug variable is passed to the model's method in the second method. The model is using this slug to identify the news item to be returned.

Now the data is retrieved by the controller through our model, but nothing is displayed yet. The next thing to do is passing this data to the views.

```
public function index()
{
    $data['news'] = $this->news_model->get_news();
    $data['title'] = 'News archive';

    $this->load->view('templates/header', $data);
    $this->load->view('news/index', $data);
    $this->load->view('templates/footer');
}
```

The code above gets all news records from the model and assigns it to a variable. The value for the title is also assigned to the `$data['title']` element and all data is passed to the views. You now need to create a view to render the news items. Create `application/views/news/index.php` and add the next piece of code.

```
<?php foreach ($news as $news_item): ?>

    <h2><?php echo $news_item['title'] ?></h2>
    <div class="main">
        <?php echo $news_item['text'] ?>
    </div>
    <p><a href="<?php echo $news_item['slug'] ?>">View article</a></p>

<?php endforeach ?>
```

Here, each news item is looped and displayed to the user. You can see we wrote our template in PHP mixed with HTML. If you prefer to use a template language, you can use CodeIgniter's Template Parser class or a third party parser.

The news overview page is now done, but a page to display individual news items is still absent. The model created earlier is made in such way that it can easily be used for this functionality. You only need to add some code to the controller and create a new view. Go back to the news controller and update `view()` with the following:

```
public function view($slug = NULL)
{
    $data['news_item'] = $this->news_model->get_news($slug);

    if (empty($data['news_item']))
    {
        show_404();
    }

    $data['title'] = $data['news_item']['title'];

    $this->load->view('templates/header', $data);
    $this->load->view('news/view', $data);
    $this->load->view('templates/footer');
}
```

Instead of calling the `get_news()` method without a parameter, the `$slug` variable is passed, so it will return the specific news item. The only things left to do is create the corresponding view at `application/views/news/view.php`. Put the following code in this file.

```
<?php
echo '<h2>'. $news_item['title']. '</h2>';
echo $news_item['text'];
```

Routing

Because of the wildcard routing rule created earlier, you need need an extra route to view the controller that you just made. Modify your routing file (application/config/routes.php) so it looks as follows. This makes sure the requests reaches the news controller instead of going directly to the pages controller. The first line routes URI's with a slug to the view method in the news controller.

```
$route['news/(:any)'] = 'news/view/$1';
$route['news'] = 'news';
$route['(:any)'] = 'pages/view/$1';
$route['default_controller'] = 'pages/view';
```

Point your browser to your document root, followed by index.php/news and watch your news page.

10.17.3 Create news items

You now know how you can read data from a database using CodeIgniter, but you haven't written any information to the database yet. In this section you'll expand your news controller and model created earlier to include this functionality.

Create a form

To input data into the database you need to create a form where you can input the information to be stored. This means you'll be needing a form with two fields, one for the title and one for the text. You'll derive the slug from our title in the model. Create the new view at application/views/news/create.php.

```
<h2>Create a news item</h2>

<?php echo validation_errors(); ?>

<?php echo form_open('news/create') ?>

    <label for="title">Title</label>
    <input type="input" name="title" /><br />

    <label for="text">Text</label>
    <textarea name="text"></textarea><br />

    <input type="submit" name="submit" value="Create news item" />

</form>
```

There are only two things here that probably look unfamiliar to you: the form_open() function and the validation_errors() function.

The first function is provided by the form helper and renders the form element and adds extra functionality, like adding a hidden CSRF prevention field. The latter is used to report errors related to form validation.

Go back to your news controller. You're going to do two things here, check whether the form was submitted and whether the submitted data passed the validation rules. You'll use the form validation library to do this.

```
public function create()
{
    $this->load->helper('form');
    $this->load->library('form_validation');

    $data['title'] = 'Create a news item';
```

```
$this->form_validation->set_rules('title', 'Title', 'required');
$this->form_validation->set_rules('text', 'text', 'required');

if ($this->form_validation->run() === FALSE)
{
    $this->load->view('templates/header', $data);
    $this->load->view('news/create');
    $this->load->view('templates/footer');

}
else
{
    $this->news_model->set_news();
    $this->load->view('news/success');
}
}
```

The code above adds a lot of functionality. The first few lines load the form helper and the form validation library. After that, rules for the form validation are set. The `set_rules()` method takes three arguments; the name of the input field, the name to be used in error messages, and the rule. In this case the title and text fields are required.

CodeIgniter has a powerful form validation library as demonstrated above. You can read more about this library [here](#).

Continuing down, you can see a condition that checks whether the form validation ran successfully. If it did not, the form is displayed, if it was submitted **and** passed all the rules, the model is called. After this, a view is loaded to display a success message. Create a view at `application/view/news/success.php` and write a success message.

Model

The only thing that remains is writing a method that writes the data to the database. You'll use the Query Builder class to insert the information and use the input library to get the posted data. Open up the model created earlier and add the following:

```
public function set_news()
{
    $this->load->helper('url');

    $slug = url_title($this->input->post('title'), 'dash', TRUE);

    $data = array(
        'title' => $this->input->post('title'),
        'slug' => $slug,
        'text' => $this->input->post('text')
    );

    return $this->db->insert('news', $data);
}
```

This new method takes care of inserting the news item into the database. The third line contains a new function, `url_title()`. This function - provided by the URL helper - strips down the string you pass it, replacing all spaces by dashes (-) and makes sure everything is in lowercase characters. This leaves you with a nice slug, perfect for creating URIs.

Let's continue with preparing the record that is going to be inserted later, inside the `$data` array. Each element corresponds with a column in the database table created earlier. You might notice a new method here, namely the `post()` method from the input library. This method makes sure the data is sanitized, protecting you from nasty attacks from others. The input library is loaded by default. At last, you insert our `$data` array into our database.

Routing

Before you can start adding news items into your CodeIgniter application you have to add an extra rule to `config/routes.php` file. Make sure your file contains the following. This makes sure CodeIgniter sees ‘create’ as a method instead of a news item’s slug.

```
$route['news/create'] = 'news/create';
$route['news/(:any)'] = 'news/view/$1';
$route['news'] = 'news';
$route['(:any)'] = 'pages/view/$1';
$route['default_controller'] = 'pages/view';
```

Now point your browser to your local development environment where you installed CodeIgniter and add `index.php/news/create` to the URL. Congratulations, you just created your first CodeIgniter application! Add some news and check out the different pages you made.

10.17.4 Conclusion

This tutorial did not cover all of the things you might expect of a full-fledged content management system, but it introduced you to the more important topics of routing, writing controllers, and models. We hope this tutorial gave you an insight into some of CodeIgniter’s basic design patterns, which you can expand upon.

Now that you’ve completed this tutorial, we recommend you check out the rest of the documentation. CodeIgniter is often praised because of its comprehensive documentation. Use this to your advantage and read the “Introduction” and “General Topics” sections thoroughly. You should read the class and helper references when needed.

Every intermediate PHP programmer should be able to get the hang of CodeIgniter within a few days.

If you still have questions about the framework or your own CodeIgniter code, you can:
